In all since October 3rd there have been seven fresh cases detected, and in each instance the Board of Agriculture officials have taken prompt steps. The infected animals, and those which had been in immediate contact with them, have been slaughtered, and their carcasses cremated in specially provided pits in the fields in which the stock were killed. The farmers in the district are viewing the situation with a fair amount of optimism, and are loyally obeying the restrictions which the Board of Agriculture have deemed wise to impose. The Board has a staff of nearly twenty inspectors on the scene, and that such a number is essential those familiar with the thorough manner in which the Board have dealt with the outbreaks are convinced. For instance, the officials, after great labour and patience, have traced practically the whole of the sheep and cattle which were sold at the recent St. Matthew's Fair, and have inspected the animals with a view to ascertaining whether any have developed the disease, the origin of which is developed in complete mystery. The inspectors have also made every endeavour to discover how the disease found its way amongst Mr. Rawle's stock, but up to the present no clues of a reliable nature have been disclosed.

Entrance to the fields in which the disease has been detected amongst stock is rigidly forbidden, and police are on duty day and night, and for the convenience and comfort of the officers temporary huts have been erected, and small stoves provided. The inspectors are clothed in overalls, and they and the slaughterers and labourers engaged in keeping the pit fires alight rinse hands and boots in carbolic before leaving, whilst the wheels of carts on which the dead stock have been conveyed to the pits for cremation are also washed in the same disinfectant. Straw is strewn in large quantities at the entrance to each of the infected fields, and hourly this is well sprinkled with Jeyes' disinfectant. Those in the locality are loud in praise of the splendid efforts which the Board's inspectors are making to stamp out one of the worst diseases that troubles the agricultural community. Almost hourly reports of suspected cases arrive at headquarters, and inspectors are despatched by motor to investigate the case. So thoroughly alarmed have many of the farmers become that the least ailment amongst stock is construed into the existence of foot-and-mouth disease, and on several occasions rumours have been in circulation that cattle are infected, when thorough examination has revealed merely the existence of a complaint common to stock.

Owing to the prolonged drought and the consequent shortage of grass in many parts of the county, farmers in the late summer were everywhere seeking keep for their stock. The moors in the Sedgemoor district being lowly situated had retained their verdancy to a remarkable degree, and to its green pastures agriculturists from a long distance away had driven their herds while their own fields recovered from the effects of the scorching sun. The consequence is that the rich moors around Middlezoy, Westonzoyle, and Othry are stocked with cattle to an extent unknown for many years, and it is, unfortunately, in the heart of this vast feeding ground that the disease has broken out. Up to the present the cases that have occurred have been in a well-defined belt of country, and in all, save one instance, the infection has been traced to contact with the originally diseased cattle. The exception was the outbreak which was reported on Friday in a field situate be-

tween Othery and Aller, a distance of nearly two miles from the original outbreak. Here eight dairy cattle were found to be suffering from the disease. These animals had not been in contact with any of the originally diseased stock. The outbreak is said to be the most virulent with which the Board have had to deal for thirty years.

The veterinary inspectors of the Board of Agriculture have paid visits of inspection to those farms visited by Mr. Bovett, on Sept. 28th, with negative results: after visiting the farm he at once returned home and thoroughly disinfected himself, his ropes, dog cart, and horse's feet before visiting other cattle.—*The Bridgwater Mercury*.

The Board of Agriculture and Fisheries has issued the following:—

No outbreak of the disease has up to the present been discovered on premises outside the two adjoining parishes of Middlezoy and Othery, near Bridgwater, but within the former parish the existence of the disease has now been confirmed amongst the stock of nine different owners, whilst one outbreak has been detected in the parish of Othery in marshes which adjoin those in the neighbouring parish in which the disease has appeared.

The outbreaks, ten in all, have occurred amongst cattle pastured in the marshes within a radius of about a mile of the village of Middlezoy, and the later outbreaks are believed to be connected directly or indirectly with the original outbreak which occurred at Manor Farm on the 29th ult.

All the cattle and sheep pastured in the fields in which the disease has appeared have been slaughtered by order of the Board, and in certain cases cattle in the adjoining pastures have also been slaughtered with a view to prevent the further spread of the disease.

Animals in the vicinity are kept under daily observation by the veterinary inspectors of the Board with a view to the early detection of any further cases of the disease.

In view of the fact that the disease has been confined to a comparatively restricted area, an Order has been made which comes into force on October 12th modifying substantially the restrictions in force in the scheduled district as regards those parts of it more remote from the outbreaks.—*The Times*.

Cruelty Charge at Eastbourne.

At the Eastbourne Borough Bench on Monday, Oct. 9th, before Mr. A. Mayhew (in the chair), and other Magistrates, Frederick Feast, of Kilburn Terrace, was summoned for cruelty to a horse on the 16th September, and Frederick J. Tompsett, of Dudley Terrace, for aiding and abetting.

Mr. F. W. Morgan appeared on behalf of Feast.

P.C. Copping stated that he saw Feast driving a grey horse attached to a landau. The horse was going very lame and he stopped it. Witness said to Feast: "Are you aware it was stopped on 14th inst., and certified unfit for work?" The reply was "Yes." Feast refused to take the animal out of the shafts, and witness and another constable had to do this. The horse was only fit for the kennels, for it had no power in its fore legs and knocked its fetlocks together. On the following morning witness went to the stables and saw Tompsett, who said, "The horse has nothing to do with me. I sold it to Feast on Friday."

P.S. North also described the condition of the animal, which he thought was aged and in poor condition.

P.C. Reader Grey gave similar evidence, adding that he saw Tompsett on 16th September, and was told, "It has not been worked with my knowledge."

Inspector Bennett, R.S.P.C.A., deposed that upon examining the animal on 17th September he found that

it had no muscular control at all over its fore legs. Tompsett told him: "I sold the horse to Feast on Friday night, and he can do what he likes for it. I have got a receipt for it." Feast admitted to him that the horse was lame, adding, "What am I to do; I've got to get a living." Tompsett said that he still let the horse stop in his stable and looked after it. He also lent Feast the landau. Feast told witness that he gave Tompsett £12 for the animal, but in the Inspector's opinion it was not worth a quarter of that amount.

Evidence was also given by David Arnold, blacksmith, of Longstone Road, and John William Bannister, blacksmith, of Leslie Street. The latter said that Tompsett paid him for shoeing the horse.

DEFENCE.

Feast, on oath, said he was "born with horses" and had had experience of them all his life. Regarding the horse in question, he said he bought the animal from Tompsett on September 15th on the advice of Mr. Wallis, veterinary surgeon, who valued it at between £12 and £15. It was not lame, and was quite fit for work with the exception of a corn.

By the Chairman: He had been in Tompsett's employ about a year. He borrowed the money from Tompsett to pay for the shoeing.

Mr. J. E. Wallis, veterinary surgeon, of Hailsham, deposed that he examined the horse on 15th September, and was told that it "ought to be shot" according to the police. But he only found a corn on each foot. He told defendants how to have it shod so as to make it go sound. Witness totally disagreed with the evidence of the inspector and police officers, and could not understand why the horse was stopped a second time. The only trouble was "corns due to bad shoeing." Witness again saw the horse on 18th September, and it was still going sound.

Mr. P. Perkins, veterinary surgeon, of Hastings, stated that he had examined the horse that morning. It was not lame nor in poor condition, and it was quite fit for work. There could not have been any wasting of the muscles of the legs.

By the Chairman: Witness would accept the opinion of a policeman as to the lameness of the horse in one leg, but not as to both fore legs.

The Bench inspected the horse, and then found the cases proved.

There was a further summons against Tompsett for cruelty to the horse on 14th September.

The evidence was to the effect that defendant was driving the horse attached to a landau, and it was in the condition that had been described. Tompsett told P.C. Copping that the horse had "knocked himself."

Tompsett was given an excellent character covering a period of 24 years, and Inspector Bennett told the Bench that he was "led away by the smoothing tongue of the man Feast."

Feast: Hear, hear!

The Bench fined Feast 15s. inclusive, and Tompsett 10s. and 5s. inclusive.—*Sussex Daily News*.

Case of Identity

A case relating to the ownership of a foal and presenting unusual features has just been heard at Bangor County Court. The plaintiff, William Pritchard, a cattle dealer, and the defendant, Hugh Roberts, both had pony mares which grazed on the mountain and were due to foal about the same time. When their owners visited the mountain to ascertain the condition of the ponies they found that both had foaled. Both mares were suckling one foal, and a dead foal was found in a river close by. A question arose as to the ownership of the foal, and the plaintiff sued the defendant for the value of the foal, £3 10s., with £1 by way of damages.

It was suggested by the plaintiff that the foal should remain with the two mares for some months, by which time it would be able to recognise its true mother; if it did not it should then be sold and the money divided, but the defendant declined. The defendant also declined to allow two independent men to decide the ownership. The plaintiff said that the defendant removed the mare and foal from the mountain to a farm, and when the plaintiff took his mare near the farm the animal neighed and the foal came up to the gate and tried to suck it, while the defendant's mare did not stir from the bottom of the field. The defendant said he pulled the dead foal out of the river and plaintiff's mare went up to it and licked it, whilst his own mare took no notice of it. The Judge thought the defendant had acted unwisely, especially in view of the dispute pending, in taking the foal from the mountain. He awarded the plaintiff £3 10s. the value of the foal, with 10s. damages.—*The Times*.

"The Senses" in Surgery.

The art and craft of surgery in some respects has not progressed during the last century as markedly as the science of surgery; for we find, for example, few novelties and still fewer improvements in the manipulative surgery of the face and extremities.

Human knowledge has its limits, and unless we can prove that man's brains grow larger as the world around him becomes more highly developed, our advance now simply means that we rely more on extraneous aid than in the greater perfecting of men's individual powers. Conversely, it is quite possible that mere mechanical development may have the opposite effect, and the brains shrink as they become less necessary.

In the practice of the art of surgery, as well as in that of medicine, I have often been struck by the clear diagnosis which those who possess a good ear for music often make where others have failed for want of it. Others having mechanical gifts will improvise an apparatus, while another man is wondering how soon he will be able to get an appliance from an instrument maker. In the matter of drawing, again, one who has a good eye for it will usually make a neater, if not a better, operator than the man who has not; his lines will be more accurate, and the ends of his incisions will meet at the proper point, and his whole work will be more perfect. So, again, with the sense of touch; this requires a long education, but some never seem to acquire any delicacy of touch—their fingers are "all thumbs," and often they will endeavour to discover by force what can only be made out by the utmost gentleness in manipulation. For example, a movable kidney or other easily displaced tumour can often be made out only by a "surprise touch," and escapes at once from observation with any rough handling. A keen sense of touch is invaluable to the surgeon; a gynaecologist especially is very much dependent upon it for success.—[From an address by W. D. Spanton, F.R.S.E.] *B. M. J.*

The Transmission of Cretinism.

Dr. Lemierre, in the *Gazette des Hôpitaux*, reports the conclusions arrived at from the studies of Von Aichbergen on the transmission of cretinism from man to animals. This author has for many years made a study of cretinism in Styria, and is convinced that the affection must be ranked among the infectious diseases. He had the opportunity of observing two dogs brought up by a female "demicretin," who made them sleep in her own bed. In course of time the dogs developed cretinous characteristics. Badly developed, they presented voluminous goitres, their coats were dull, dry, and lanuginous, and they retained their milk teeth. They were unable to bark and appeared devoid of all

intelligence. The author next entrusted this woman with a young dog obtained from an absolutely healthy litter, without hereditary pathological taint. The young animal took up the same style of living as the two others removed from the house. Three months later it also had a goitre, but was still lively and able to bark. Ten months later the goitre had become enormous, the animal was apathetic and incapable of barking. Its coat had lost its gloss, and its milk teeth remained. In short, it presented the appearance of a cretin. On the other hand, a dog of larger breed entrusted to the woman and brought up in the same room as its companion, but without sleeping in the same bed, developed on normal lines. The author thinks that these facts demonstrate that the transmission of cretinism from man to animals is possible.—*The Hospital*.

The Vitality of Ascaris Ova.

Dr. R. S. Morris, writes on this subject in the *Johns Hopkins Hospital Bulletin*. In the clinical laboratory of that hospital are preserved jars containing a thin suspension of faecal material and parasitic ova. The dilution with formalin and water is so arranged that there is present 2 per cent. of the antiseptic. This strength was believed to be lethal to the ova of every parasite affecting human beings, and Dr. Morris's experience shows that this is true of all except *Ascaris lumbricoides*. In January, 1909, when demonstrating from one of these jars, he was astonished to find that many of the eggs contained actively motile embryos. How long the specimen had been on the laboratory shelf is unknown, but the embryos were still motile in May of this year—that is, twenty-nine months after they were first noticed to be alive. In December, 1909, the author had an opportunity to test the accuracy of his observation, as a patient was admitted whose faeces swarmed with the ova of *Ascaris*. A specimen was put up in 2 per cent. formalin, securely sealed in a jar of brown glass, and left on the laboratory shelf. Twice in 1910 search was made for motile embryos without result, but in January, 1911, a few were found, and in May another examination showed an apparent increase of the number.

Personal.

Mr. WILLIAM SHIPLEY, F.R.C.V.S., of Yarmouth, who has succeeded Mr. W. Freeman Barrett as Hon. Secretary of the Victoria Veterinary Benevolent Fund, has been successful in aiding this excellent institution by means which might with advantage to the Fund be emulated in other places. Mr. Shipley arranged a bowling tournament in which he interested a number of his friends, one of whom, Mr. D. E. Aldred, kindly presented a silver cup for competition. Twenty-six players took part on Thursday, Sept. 28, and the result of the tourney was that Mr. Ernest B. Blake, J.P., won the cup. The players were entertained to tea by Mr. and Mrs. Shipley. From the sale of the tickets, and subscriptions obtained through the tournament, the sum of £8 7s. 6d. was put to the credit of the Victoria Veterinary Benevolent Fund.

OBITUARY.

ROBERT LEES, M.R.C.V.S., Lagg, Ayr.

Graduated, 1862, Edin: 1880.

Mr. Lees died on Thursday, 28th ult. Aged 68 years.

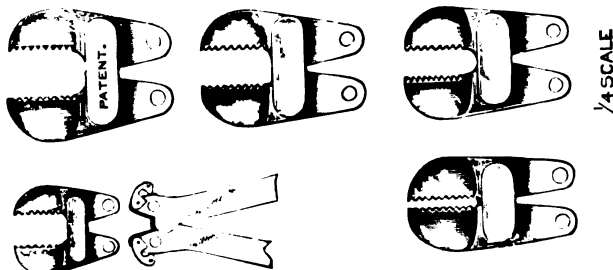

EDWARD BAILEY, M.R.C.V.S., Leicester, Vet.-Maj. Leicestershire Yeomanry Cavalry. Lond: April, 1859.

Death occurred on Oct. 5th, from bronchitis, at the age of 73 years.

The EXAMINATIONS are officially recognised as qualifications for appointments by Government Departments and Municipal Authorities.

COURSES OF LECTURES for Candidates preparing for the Examinations are held by the Institute in London in the Spring and Autumn.

Application Forms and full particulars can be had from the Secretary, 90 Buckingham Palace Road, London, S.W.

Practices for Disposal

GOOD-CLASS General Practice in first-class sporting district in the South Midlands, represented as returning between £450 and £500 p.a. is for disposal under satisfactory reasons. Further particulars in confidence will be given on application.

OLD established practice is for immediate sale, vendor having obtained an appointment. Situate in the Eastern Counties. Good agricultural district. Returns represented as being £450 p.a. C.C. inspectorship. Excellent house and stabling. Two acres of grass paddock. Price, in order to secure quick sale, £300, to include drugs, fittings, instruments, trap and cob.

AN exceptional investment for a smart man desirous of South African Practice. An opportunity of securing a partnership in an excellent equine and canine practice, established for 18 years. Represented as returning on average for last three years over £1000 p.a. Letter just to hand states: returns for first 6 months this year have been £607 10s., and that this is capable of great increase. Capital required (to include half-share of practice and valuation of surgery) under £600. References exchanged. Further information will be given to bona-fide applicants.

Wanted

PARTNERSHIP, with view to succession, in a good-class sporting practice, desired by an experienced M.R.C.V.S. with capital at command. Good horseman. Particulars will be received in strictest confidence.

PRACTICES FOR DISPOSAL

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

LONDON, W. Good-class practice returning about £600 per annum, with forge the gross returns from which are stated to be about £1000 per annum. Working expenses are exceptionally low. Convenient, well-situated house, rent £70 inclusive. Forge rent £69. Contracts produce about £300 per annum and could be greatly increased by practitioner willing to accept lower fees. Premium £1000.

CHESHIRE. Practice in good breeding and hunting district, returning £600 per annum. In present hands 10 years. Convenient house with surgery, stabling etc., rent £55. Premium one years purchase.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

HEALTH RESORT. Practice returning £650 per annum, chiefly dog. Good house with large yard, stabling, kennels, etc., rent £85, or would sell freehold. Premium £750. Valuation optional.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

M.R.C.V.S. disengaged until Christmas desires position as locum or temporary assistant. Address, 3106 V.R., 20 Fulham Rd., London, S.W.

Partnership

THOROUGHLY reliable, practical V.S., age 33, desires partnership, view to succession, or would buy practice or nucleus in a good hunting country. Address, 3109 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

Partner Wanted

ADVERTISER, who has well established canine, etc., practice in London, is about to start canine sanatorium, wishes to meet practical canine V.S. to join him. Excellent opportunity, unlimited scope. Moderate capital required. Further information to bona-fide applicants. J. Kelsey, 35 Anstey Rd, Herne Hill, S.E.

Wanted

DECENT veterinary surgeon to take over a sound practice, returning £420 and increasing yearly, principal wishing to retire. Very moderate price, easy payments and a good introduction given. Address, 2102 V.R., 20 Fulham Road, London, S.W.

For Sale

PRACTICE in best breeding district in Cumberland. Been in family nearly fifty years. No opposition. Good introduction given. Full particulars on application Address, 1101 V.R., 20 Fulham Road, London, S.W.

As Manager, Assistant or Locum

QUALIFIED veterinary surgeon, experienced both town and country, wishes post as locum, manager or assistant, indoor or out. First-class references. Address, 5097 V.R., 20 Fulham Rd., London, S.W.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34, single. Excellent references, interview. Address, 5074 V.R. 20 Fulham Road, London, S.W.

AGENTS REQUIRED in unrepresented districts for the **IMPERIAL ACCIDENT INSURANCE CO., LD.** Est., 1878. Horses Insured against Death from Accident or Disease, Mares for Foaling and Loss of Foals; Farmers' Liability for Accidents to Labourers, Servants, and Workmen's Compensation. Claims paid, £500,000. Address Agency Manager, 17, Pall Mall East, London, S.W.

For Immediate Disposal

YORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment: introduction given. Address, 5092 V.R., 20 Fulham Road, London, S.W.

Instruments for Sale

FIVE gross best German silver teat syphons, three sizes, 4/6 per dozen. Alumina vulva clamps 5/6. Hernia clamps, Alumina, 4/6, any length. Cotton hobbles 12/6 per set. Ask for prices. Send on Repairs. Malloch, M.R.C.V.S. Instrument Maker, Kirkby Stephen.

Victoria Veterinary Benevolent Fund**President:**

W. F. BARRETT, Esq., Fountain Court, Temple, E.C.

FUNDS are urgently needed to enable the Society to extend its relief to distressed Members of the Profession, or to widows and orphans of deceased veterinary surgeons. Annual subscriptions, or donations will be gratefully acknowledged by the Hon. Sec. and Treas.

W. SHIPLEY, Southtown, Great Yarmouth.

Assistant Unqualified)

SON of V.S. aged 26, seeks situation, experienced mixed town and country practice, well up in all branches. Energetic, good dispenser and book-keeper. Ride, drive and cycle, not afraid of work. Present situation 18 months, excellent references. Disengaged October 28th W. Andrews, c/o Wartnaby & Sadler, 89 Horninglow Road, Burton-on-Trent.

Change of Address

W. T. BROOKES, M.R.C.V.S.,
Veterinary Infirmary and Shoeing Forge,
The Butts, Warwick.
Late 20 Jury Street, Warwick.

For Disposal

WARWICK, freehold house (or lease) 20 Jury Street. Veterinary surgeon's business carried on upon premises for over 50 years, in main street, country town, good hunting district. 3 reception, 6 bedrooms, bath, large yard in rear. 5 loose boxes, stall, large shoeing forge, saddle room, loft, surgery. Ledbrook, Solicitor, Warwick.

To Veterinary Surgeons

ADVERTISER, ex-student with extensive experience, well up in all branches, wishes to join veterinary surgeon in or near London and assist him in his practice Single: live in or out: terms moderate. Address, 1104 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H.J. Pratt, Wholesale Druggist, Cleckheaton.

CHEAP BOTTLES.

3oz. and 4oz. 6/- per gross, 6oz. and 8oz. 7/-, 10oz. and 12oz. 9/-, 1oz. W. F. Vials 4/- 1½oz. do. 4/6, 2oz. do. 5/- per gross. Cash with order. All sizes in Poison and other bottles and jars quoted for, also a quantity of 4, 6, and 8oz. named medicals 5/6, 12, and 16oz. 7/- per gross. Carriage paid on orders within 70 miles.

F. NEEDHAM,

Beaconsfield Road, Acton Lane,
Chiswick, London, W.

GLANDERS

A Clinical Treatise, by William Hunting, F.R.C.V.S.

Chief Veterinary Inspector to the London County Council.

SOME PRESS NOTICES:

THE HOSPITAL.

"The treatise is complete without diffuseness, scientific without being unpractical, and throughout eminently lucid. Of the appendix on glanders in man we will only say that we could wish it reproduced in text books of medicine just as it stands. The book is excellently produced, and illustrated with a series of coloured plates by Mr. S. A. Sewell which are well worthy of the letterpress."

THE BRITISH MEDICAL JOURNAL.

"The book is the outcome of unique opportunities and from the clinical and hygienic point of view it is extremely valuable. . . . One of the most valuable features of the book is a series of fourteen beautifully executed coloured plates showing typical lesions of glanders in horses."

THE VETERINARY JOURNAL.

"To praise it too highly would be impossible, for nothing equal to it has ever appeared before, and even our continental colleagues must yield on this occasion. . . . The coloured plates and photographs are simply superb."

THE FIELD.

"This book should be found in every public library, and no medical student should fail to assimilate its contents. It will doubtless find a place in the library of country gentlemen and all who take a deep interest in the horse."

THE VETERINARY NEWS.

"For the work itself we have nothing but the highest praise. The printing is excellent, the plates could not be excelled, and the binding is on a standard with the rest of the work."

THE SCOTTISH FARMER.

"This is a splendidly got up volume and evokes admiration. We trust the enterprise of author and publishers in issuing such a work will be richly rewarded."

THE JOURNAL OF COMPARATIVE PATHOLOGY.

"For many years past Mr. Hunting has been generally recognised as the chief authority in this country on glanders regarded from a clinical point of view, and in this monograph he has given the profession the benefit of his long and intimate study of the disease. . . . The book will prove well-nigh indispensable both to veterinary students and practitioners."

COUNTY GENTLEMAN.

"The best book on glanders."

THE SCOTSMAN.

"The volume is an evidence of the high competence which veterinary science has reached."

LIVE STOCK JOURNAL.

"The volume deals with glanders in all its phases, and also with the dangers of infecting human subjects with this disease."

THE NORTH BRITISH AGRICULTURIST.

"This is a massive and handsomely got up work by a man who thoroughly understands his subject."

THE FARMER'S GAZETTE.

"In the appendix is an interesting account of glanders in man A prominent feature of the book is the beautifully reproduced water-colour drawings. The colouring of these is very true to nature."

THE MORNING POST.

"Mr. Hunting is Chief Veterinary Inspector to the London County Council. The post-mortem examinations made for that body have furnished him with a unique collection of glanders lesions."

THE SPORTSMAN.

"For this valuable work Mr. Hunting deserves the thanks of all horse-breeders and owners. . . . Much has to be done before we finally get rid of glanders, and to this desirable consummation Mr. Hunting has contributed splendid assistance by the book under notice."

THE ROYAL DICK COLLEGE MAGAZINE.

"The veterinary profession, not only in the United Kingdom but throughout the world, is greatly indebted to Mr. Hunting for putting the results of his experience on record and within the reach of all. . . . The illustrations alone are an invaluable addition to the library of any practitioner, and their educational value to the student will be fully appreciated."

THE VETERINARY RECORD.

"If the text is a mine of clinical wealth, the photographic and coloured plates are examples of the highest artistic talent. Nothing like them has ever previously been attempted in connection with glanders. To the present generation they indicate in the most natural manner what many men never have seen, while to posterity they will remain a record of a loathsome disease which in time will be as dead in these islands as pleuro-pneumonia or rabies."

The publisher is to be congratulated on his share of the work—good paper, fine print and admirable binding combine to make a handsome volume."

THE JOURNAL OF ECONOMIC BIOLOGY.

"There is little doubt but that so valuable a contribution to the literature of veterinary pathology will find a place in the library of everyone who has to deal with diseases of the horse. It is ably written, and leaves nothing to be desired in the manner in which it has been presented to the public."

THE ESTATE MAGAZINE.

"Probably the most authoritative and comprehensive work on glanders that has yet seen the light."

THE LANCET.

"The work under review will be the standard work of reference on this dreadful scourge of the equine world for many a year if we mistake not. . . . The subject is treated from every point of view which is likely to be of value, and this small book is equally of interest to members of the medical and veterinary professions. No medical officer of health and no hospital library should be without it."

Cloth, Lettered, 10/6 net.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1215.

OCTOBER 21, 1911.

VOL. XXIV.

THE COUNCIL MEETING.

The recent Council meeting was a quiet one. For the most part its proceedings consisted of routine business, and present few features of interest.

Foremost, of course, come the financial difficulties. As is now usual, the Treasurer made a short speech summarising the position, probably for the benefit of members outside the Council Chamber. At the July Council meeting that speech was full of gloomy predictions, which are now justified by the statement at last week's assembly. Consols have been sold—£1,000 worth—but the bulk of the proceeds of the sale has gone to repay the bankers' overdraft, leaving only some £370 now in hand. The ensuing quarter's bills are expected to absorb nearly half of this small amount, and in all probability, therefore, the Treasurer will have to ask at next January's meeting for authority to sell another £1,000 worth of Consols. This second sale will carry us on a little longer than the one just concluded, for there is now no banker's overdraft to pay off, but its proceeds cannot last for very long. And this is the direction in which the College finances must inevitably move, until the passage of the pending Bill.

Very little is to be recorded as to the progress of the Bill. Further correspondence has taken place with the Highland and Agricultural Society, whose objection to the measure seems now to have narrowed down to one point; and the Bill itself, which was crowded out in the last Parliamentary Session, is to be re-introduced in the next one. Last Session was so congested that this one cannot be expected to be a normal one; and the Bill will require some luck at the ballot to ensure it against a repetition of its former fate.

Very little need be said of the remainder of the business. The examination Committee has been instructed to revise the syllabus for the professional examinations, with power to consult with the teachers and examiners in doing so; and notice has been given of a series of alterations in the bye-laws relating to examinations. Both these matters can be better considered later. Finally, we note one brief item in the report, which is very important and altogether welcome. The Council has approved the Draft Ordinance of Edinburgh University for degrees in veterinary science. Edinburgh University proposed to institute such degrees several years ago, on lines unacceptable to the R.C.V.S., and the scheme fell through. It has now been revived in an amended form; and the Council's resolution marked one step forward towards the establishment of Veterinary University Degrees in Scotland—a thing which we shall all be glad to see.

THE RÖNTGEN RAYS IN THE DIAGNOSIS OF PULMONARY TUBERCULOSIS.

Prof. Levy, of Dorn, publishes (*Berliner Klin. Wochenschr.*) an account of a series of observations upon patients, in which the Röntgen rays were used in combination with ordinary clinical methods for the diagnosis of pulmonary tuberculosis. Thirty-two patients in all, selected indiscriminately, came under observation. The object of the investigation was to ascertain whether, by the help of the Röntgen rays, the diagnosis could be made earlier and more completely than by clinical methods alone. The results showed that the Röntgen rays are of great value in the early diagnosis of pulmonary tuberculosis, and that only in a few cases did they fail to expedite the diagnosis.—(*Berliner Tier. Woch.*)

DUMB RABIES IN CATTLE.

Max Hecksch, of Gyula, report (*Allatorvosi Lapok*) an outbreak of this disease, which killed eleven cows of a valuable herd within two weeks. The symptoms were as follows:—

The animals stood with their limbs straddled apart, and leaned their heads or necks upon the bars of the stall. They executed masticatory movements when no food was in their mouths, salivating copiously meanwhile. The temperature was from 103.1 to 103.4 F.; the pulse was weak, and about 56 to the minute. Peristalsis was sluggish. The pupils were widely dilated. Reflex irritability was heightened.

Microscopical examination of the blood gave negative results. Post-mortem examination of the animals which died only revealed hyperæmia of the brain and its membranes. Infectious cerebro-meningitis was suspected, though no stiffness of the neck was to be seen. The possibility of vegetable poisoning was also considered, but this was negated by the fact that the whole of the animals received the same food, and no cases of illness appeared amongst the bullocks.

The treatment adopted was—injections of pilocarpine (in doses of 0.3 grammes, or about $4\frac{1}{2}$ grs.), cold applications to the head, and artificial nourishment.

Prof. Marek, who was called in in consultation, expressed a suspicion of dumb rabies, and it then transpired that a stray dog, about two months previously, had bitten a dog upon the farm, which had soon afterwards been shot. Experimental inoculations with material from the central nervous system from the cows confirmed the diagnosis.—(*Berliner Tier. Woch.*)

A FLAGELLATED ORGANISM ENCOUNTERED IN A VULVO-VAGINAL PUSTULO-ULCEROUS ERUPTION IN A BUFFALO.

Prof. Poenaru has recently observed, at Bucharest, a buffalo affected with a pustulo-ulcerous inflammation which spread from the vagina to the urethra and the bladder, causing violent tenesmus and a muco-purulent discharge.

Microscopical examination of the vaginal discharge and of scrapings from the ulcers revealed the presence, in the midst of a multitude of microbes, of very numerous examples of a special organism taking all the colouring agents and Giemsa's stain in particular.

This organism had the appearance of a spermatozoon, with an ovoid body from 6 to 8 micro-millimetres long, and a flagellum of from 30 to 55 micro-millimetres. The protoplasm of the body showed but little differentiation, and was covered by a cuticle.

The organism was slow in its movements; and, together with its associated microbes, lived for a long time in pure water and in sugared bouillon, especially at the bottom of the glasses in which the scrapings from the ulcers had been collected. Poenaru did not succeed, however, in either inoculating it or cultivating it.

Repeated examinations of hanging drop preparations made for a period of some days did not reveal the least multiplication of the organism.

At the end of three months, the flagellum fell away. The body of the organism still remained visible in the bouillon for some time, and then in its turn became disintegrated.

This organism evidently represents a flagellate, and seems somewhat similar to the one which Grimm, in 1894, discovered in the pus of pulmonary and hepatic abscesses in a Japanese peasant woman, and which R. Blanchard designated *Monaspyophila*, although it does not possess the small flagellum of *Monas*.

Perhaps the above described organism played a part in the development of the pustules and ulcers of the buffalo's vulva and vagina. Poenaru, however, made several attempts to infect rabbits by inoculating them in the vagina with scrapings from the ulcers, and also with the vaginal discharge; and in every case he failed to transmit the disease, the flagellates only living a few days in the vaginas of the rabbits.—(*Arhiva Veterinara*).

CHOLESTEATOMA IN A HORSE'S BRAIN.

Wester records (*Tydschrift voor Vecartsenijkunde*) a case of an old tram horse which, during his period of work upon the tramway, had never shown symptoms of illness. He was bought by a wood merchant, and at first did his work perfectly. Before long, however, he became subject to attacks of cerebral symptoms, which on several occasions necessitated professional aid.

During one of these attacks, the horse was brought to Wester. He was then greatly depressed, the head was carried low, the eyes were fixed, and progression was slightly unsteady. The pulse was

weak, but of normal frequency. The author bled the horse, taking 8 litres (about 14 pints) of blood, and advised cold douches. At the end of two days, the animal appeared recovered and resumed work.

Five months later Wester again bled the animal, the symptoms of depression having reappeared. He then learned that, in the interesting period, the horse had shown nervous symptoms at different times and that even crises of excitement had been manifested. Another veterinary surgeon, who had been consulted, had advised working the animal hard with only a moderate diet.

A few days later the horse, after having been very excited, became colicked, and slaughter was decided upon.

Post-mortem, Wester found that the occipital portion of the two cerebral hemispheres was voluminous and infiltrated; it was also transparent and gelatinous in aspect, but these two latter characteristics disappeared soon after the escape of the cerebro-spinal fluid. The two ventricles, however, remained voluminous; and were found to be distended by a bilobed tumour of a yellowish-grey colour, showing glistening points here and there, and weighing 118 grammes. Microscopical and chemical examination proved this growth to be a cholesteatoma.

The tumour was immersed in a large quantity of encephalo-rachidian fluid, which was viscous and dark in colour. The cerebral ventricles, especially the left one, had become considerably distended under the influence of the constant pressure. On that side, the cerebral material had been diminished to such a degree that the hemisphere had become transparent behind the olfactory lobes. No hæmorrhage was perceptible to the naked eye.

It is rather peculiar, the author remarks, that despite the presence of a neoplasm of such importance and the constant pressure produced by it, the symptoms of disease only appeared periodically. The author's idea is that this may be attributed to a periodic obstruction of the aqueduct of Sylvius, giving rise to a temporary accumulation of fluid in the ventricles.—(*Annales de Méd Vét.*) W. R. C.

Royal College of Veterinary Surgeons.

A quarterly meeting of Council was held at the Royal College of Veterinary Surgeons, 10, Red Lion Square, on Friday, October 13th, 1911, Prof. A. E. Mettam (President) in the Chair. The following members were present: Colonel Sir Francis Duck, K.C.B., Professors Bradley, McCall, Sir John M'Fadyean, and Shave, Messrs. Abson, Banham, Carter, Dunstan, Garnett, Hobday, Lawson, Mason, McKinna, Mulvey, Roberts, Shipley, Slocock, Trigger, and Villar; Mr. G. Thatcher (solicitor), and Mr. F. Bullock (secretary).

Apologies for Absence.

The SECRETARY announced that apologies for non-attendance had been received from Mr. Rutherford, Major-General Thomson, Mr. Wharum, Prof. Dewar, Mr. Freeman Barrett (who, through illness, had gone for a sea voyage), Mr. Sumner, and Mr. Lloyd.

MINUTES.

On the motion of Mr. Lawson, seconded by Mr. Abson, the minutes of the last meeting were taken as read and confirmed.

OBITUARY.

The SECRETARY read the obituary list.

Mr. CARTER: Perhaps I may be permitted at this juncture to propose that this Council send to the widow of the late Prof. W. Owen Williams a letter of condolence expressing the great sympathy we feel with her in her loss. I claim this privilege from the fact that perhaps I was longer acquainted with Prof. Owen Williams than any man round this Council table, indeed I may say perhaps longer than any member in the profession. I go back to the time when Prof. Williams' father was practising in Bradford, and when Owen Williams and myself were boys together. From that time up to the date of his death there was one continuous friendship between Prof. Owen Williams and myself. He was a gentleman who I am sure will be greatly missed—a gentleman undoubtedly of many talents, and a distinguished and a shining light in the profession. The whole of the time I knew Prof. Owen Williams, from his earliest boyhood, I always found him a gentleman—a cultured gentleman. He contributed from time to time to veterinary literature; and he had a quiet, dignified manner which I am sure it would be well for many to emulate. I move that a letter of condolence from this Council be sent to his widow and family.

Mr. ABSON: I should like to second the proposition so ably moved by Mr. Carter. I knew the late Prof. W. O. Williams for a goodly number of years, he being an old College friend of mine. It affords me a melancholy pleasure to second the resolution.

The PRESIDENT: Gentlemen, you have heard the remarks that have fallen from Mr. Carter and Mr. Abson, and I am sure the Council wishes to associate itself with the expressions of sympathy with the widow and family on the decease of Prof. Owen Williams. I shall not put the motion to the vote because I take it that everyone feels they have made a personal loss through the death of Prof. Williams, but I ask the Council to pass the resolution unanimously, upstanding.

The resolution was carried in silence, all the members upstanding.

Mr. ROBERTS: I should like to move that we send a vote of condolence to the widow of the late Mr. Cunningham. I knew the late Mr. Cunningham from my student days, and he was a very excellent man. He was a public spirited man so far as the profession was concerned and one who, by his kindness, sayings, and his deeds was for a great many years a man that a great many of the veterinary surgeons of the North have looked up to with admiration. I think we ought not to let this sad occasion pass without passing a resolution similar to the one we have passed with regard to the late Prof. Williams. With great sadness I propose that we do this. Mr. Cunningham was for a good many years associated with the Council as an examiner.

Prof. BRADLEY: I should very much like to be permitted to second the vote of condolence. The late Mr. Cunningham was extremely well known in Scotland, and his loss is very keenly felt.

The PRESIDENT: I am sure we all feel the loss that Mrs. Cunningham and the family have sustained in the death of Mr. Cunningham, whom I knew personally for a great number of years when I was in Scotland. The interests of the profession were always in Mr. Cunningham's heart, and he did everything in his power to further them. I am sure that the members of the Council would wish to send a vote of condolence to Mrs. Cunningham and the family on the loss they have sustained.

The vote of condolence was carried in silence, all the members upstanding.

ADMISSION TO MEMBERSHIP.

The SECRETARY announced that the following gentlemen had been admitted as members of the College since the last meeting:—

London College.—Messrs. Robert Bowes Cockburn, Thomas James Davis, James Thos. Edwards, George Verney Golding, Jas. Arthur Grounseil Gosling, Henry Epton Hornby, Frank Fielding Horton, Francis Colin Minett, Wm. Arthur Pool, Stanley Cecil Rowbotham, Gordon Frank Steevenson, and Wm. Poole Stokes.

Liverpool College.—Messrs. Thomas Craig, Geo. Guest Howard, Stuart Kirkby Jones, Peter McGregor, Fredk. James Richmond.

Dublin College.—Messrs. Herbert Wilson Carbury, John Martin Crowe, Michael Cunningham, Peter Francis Dolan, Thomas Michael Doyle, Patrick Desmond English, Patrick Joseph McCormack, Thomas Francis O'Brien, Michael John Reidy, Thos. le Blanc Revington, John Smith, and Nasli Dinshaw Vakil.

CORRESPONDENCE.

The SECRETARY read a letter he had received from the General Secretary of the Committee organising the 7th International Congress on Tuberculosis at Rome, which should have met in September, informing the Council that the Congress would be postponed until the middle of April, 1912, largely due to the fact that many of the Foreign Committee had found the month of September unsuitable. The Committee hoped that, in spite of the postponement, the College would retain the adhesion to the Congress it had already sent in.

PRESENTATIONS TO THE LIBRARY.

The SECRETARY announced that the following presentations to the Library had been made since the last meeting:—By Major F. S. H. Baldrey, F.R.C.V.S., D.P.H.: The Benefits of Sheep Dipping; A Preliminary Note on neutral red reaction in the infected red cells of Protozoal Diseases; Haemorrhagic Septicæmia of Cattle, and its relation to preventive vaccination; Aggressins in Barbone and their application as an immunizing agent; the preparation of anti-rinderpest serum by means other than the injection of virulent blood; Preventive Vaccination against Strangles; Milk Supply; Veterinary Science; Trypanosoma Lewisi in der Rattenlaus Hæmatopinus spinulosus. Dourine of Horses: Its cause and suppression, by John R. Möhler, v.m.d.; Anthrax, with special reference to the production of immunity, by Chas. F. Dawson, M.D., D.V.S.; Annual Reports of Proceedings under the Diseases of Animals Acts, the Market and Fairs (Weighing of Cattle), etc., etc., for the year 1910; Statistical and General Report of the Army Veterinary Service for 1910; Calendar of the Royal College of Surgeons, 1911; Report of Council of National Association for the Prevention of Consumption, 1911; Report of the Veterinary Surgeon to the Corporation of the City of Glasgow (Police Dept.) for 1910; Programme et Règlement de l'Exposition Internationale Temporaire de l'Industrie du Lait, October, 1911; Year Book of the Society of Tropical Medicine and Hygiene, 1911-12; The Progress in the Tuberculosis Campaign in Pennsylvania up to 1911; Resolution on the Annual Reports of the Bengal Veterinary College, 1910-11; The Rhodesian Agricultural Journal, June and August, 1911; The Journal of the Board of Agriculture, July, August and September, 1911; Supplement to The Journal of the Board of Agriculture, July, 1911; Leaflets of the Board of Agriculture and Fisheries; The Journal of Meat and Milk Hygiene, July, August and September, 1911; Bulletins of the Sleeping Sickness Bureau, July, August, and October, 1911; Bulletin of the Yellow Fever Bureau, June, July, August, and

September, 1911; *Revue de Pathologie Comparée*, June, July, August, and September, 1911; *The Journal of Comparative Pathology and Therapeutics*, June and September, 1911; *The Journal of Tropical Veterinary Science*, Vol. VI., No. 3; *The Veterinary Journal*, *The Veterinary News*, and *The Veterinary Record* for the quarter; Bound copy of *The Veterinary Record*, Vol. 23.

On the motion of Mr. Mulvey, seconded by Prof. McCall, a hearty vote of thanks was accorded to the respective donors.

FINANCE COMMITTEE.

Mr. MASON read the following report of a meeting of the Finance Committee held on Oct. 13th, 1911:

Appointment of Chairman. It was resolved that Mr. A. W. Mason be appointed Chairman of this Committee for the ensuing year.

Minutes. The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Financial Statement. The Treasurer submitted his financial statement for the quarter.

And it was resolved: (a) That the Financial statement be approved and that the Treasurer be authorised to pay the liabilities, together with cheque for monthly salaries, petty cash, fidelity insurance, Fellowship examination expenses, and electric light required during the ensuing quarter.

(b) That the account of £1 1s. 6d. for repairs to fan be referred to Treasurer, and that he be authorised to pay the account if a satisfactory explanation of the expense is received.

Trust Funds. It was resolved that the President be authorised to sign the request to the official trustees of charitable funds for the remittance of dividends received in connection with the Steel Memorial, Walley Memorial, and Jubilee Memorial Funds.

Mr. MASON: I beg to move that the report be received and adopted.

Prof. MCCALL: I second that.

Mr. TRIGGER: Before the report is adopted I think the statement in the report that "The Treasurer be authorised to pay the account if a satisfactory explanation of the expense with regard to the repairs of the fan is received" is not quite what was intended. What the Committee decided was that a satisfactory job should be made of the work. I do not think any explanation would be satisfactory that did not put the fan in order. The fan is an absolute failure and out of order, and the decision of the Council was not to pay the bill until it was made good. An explanation is not what we want. The wording of the report should have been "Until the work is satisfactorily performed."

Mr. MULVEY: As I understand the instruction it was that, until the fan was put into satisfactory working condition, the account was not to be paid.

Mr. TRIGGER: That is so. It is only a verbal alteration of the report.

Mr. MULVEY: With regard to the financial statement, I do not know that there is anything very particular that I need call your attention to, except you will notice that our income is still on the down grade, and that year by year our income from examinations becomes less. Then, again, you will notice that since our last meeting Consols have been sold, and we have been able to pay off the bank the amount they advanced, leaving us with a balance in hand after the accounts are paid to-day of some £370. But in addition to that we have to meet the demands for the next quarter's accounts, which will come to, say, about £160, so that we shall be in the position before Christmass next of having about £200 left out of our £1000 worth of Consols which we have just sold. I tell you this because I want you to be prepared for the announcement that in

the early part of next year the probabilities are I shall have to ask to sell out further Consols, unless by some miraculous means you are enabled to find funds to carry on the business of this Council.

Mr. MASON: With the verbal suggestion, I beg to move the adoption of the report.

Prof. MCCALL: I beg to second that.

The PRESIDENT: The alterations consists in an addendum—"That the account of £1 1s. 6d. for repairs to fan be referred to the Treasurer, and that he be authorised to pay the account if a satisfactory explanation of the expense is received, and when the fan is put into working order."

The resolution was then put and carried unanimously.

REGISTRATION COMMITTEE.

The SECRETARY read the report of a meeting of the Registration Committee held on Thursday, Oct. 12, 1911, which stated that the President was elected Chairman of the Committee.

Correspondence. Circulars issued by the County Live Stock Insurance Association, Ltd., to Veterinary Surgeons, offering free use of printed labels and notepaper, were considered, and it was resolved "That in the opinion of this Committee the use of such labels and notepaper by Veterinary Surgeons is to be deprecated as being in bad taste."

It was announced that a letter had been received from the Colonial Office enclosing an Ordinance to make provision for veterinary surgeons in St. Vincent, and it was resolved to recommend that the matter be referred to the Melbourne University Degree Committee.

A letter was received from the Department of Agriculture for Ireland enclosing a mallein test chart signed by Mr. G. C. Hill as a Member of the College. It was resolved that the Solicitor be instructed to prosecute.

Various other letters were considered by the Committee, and the Secretary or Solicitor instructed with regard to the actions to be taken in regard to them.

Eighteen cases were considered by the Committee, in some of which it was reported that undertakings had been received, and in others of which it was decided that no action should be taken. The Solicitor was instructed to prosecute in certain cases if proper evidence was obtainable, and in one case it was resolved that a Member should be called upon to appear at the next meeting of the Committee to show cause why his name should not be removed from the Register.

Restorations. (a) An application was received from Mr. A. J. Blake for the restoration of his name to Register, it having been removed under Section 5, Sub-section (4) of the Act, and it was resolved that the name of Mr. Arthur John Blake be restored to the Register of Veterinary Surgeons.

(b) A letter was read from Mr. Albert Hassall whose name has been removed from the Register under Section 5, Sub-section (4), and it was resolved that under the special circumstances the name be restored to the Register without payment of a fee.

On the motion of Mr. Garnett, seconded by Mr. Roberts, the report was adopted; and on the motion of Mr. Mulvey, seconded by Mr. Roberts, authority was given for the Seal of the College to be affixed to the various orders for prosecution mentioned in the report.

EXAMINATION COMMITTEE.

Mr. VILLAR read the following report of a meeting of the Examination Committee held on Thursday, Oct. 12, 1911:

Appointment of Chairman. It was resolved that Mr. S. Villar be appointed Chairman of this Committee for the present year.

Minutes. The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Reports on July Examinations. The reports of the Delegates, Chairmen of the Board of Examiners, and the Local Secretaries were read and considered.

(a) A delegate at one school reported that in Class D there was no proper supervision of students performing surgical operations, so that it was possible for one student to assist another.

And it was resolved to recommend that this report be brought to the notice of the Examiners.

(b) Reference was also made to the presence of teachers at the Oral Examinations.

And it was resolved that in the opinion of this Committee it is highly improper on the part of a teacher to interfere in any way with the conduct of an examination, or to endeavour to influence the Examiners' award.

(c) Dublin examination. It was resolved that a letter of thanks be forwarded to Mr. Alfred Miller for the loan of desks for the Written examination, and to Col. Moore for the supply of horses for Class D Oral examination.

(d) It was resolved that the examination fee of Mr. H. T. Wright, who was unable to attend through illness at the examination in July, be held over until December next.

Educational Certificates. Educational Certificates numbered 1187 to 1192 were submitted and approved.

Examination Bye laws. Bye-laws numbered 56 to 84, revised at the previous meeting, were submitted and provisionally approved, the Chairman undertaking to give the usual notice as required by the Charters.

Edinburgh University Ordinance. The draft Ordinance for the award of Degrees in Veterinary Science by the University of Edinburgh was considered and approved.

Mr. VILLAR: I beg to move that the report be adopted.

Mr. MASON: I beg to second that.

Mr. GARNETT: There is one point in the report with regard to the Examination Bye laws to which I should like to refer. I do think it would be a very good thing if the whole of the Examination Bye-laws could be carefully gone through, more especially with regard to those bodies which have the power to issue preliminary licences which are accepted by this Council. It is well-known that we require our students to pass at their Preliminary Examinations all the subjects at one time, and that the standard should be the same as that which will admit a student who is taking up ordinary medicine without the necessity of passing the same subjects all at one time. I do think that we should place our students on the same level as medical students, and that we should not require of them a harder test in the Preliminary Examination than is insisted upon by the General Medical Council. For that purpose I would like to suggest that the matter I refer to be sent to a special committee, who will go into the whole question thoroughly, and give our students the same opportunities of passing their Preliminary Examinations that are accorded by the Medical Council to medical students. I would also like to suggest, in order that there might be no misconception that I want in any way a lower standard for the candidates, to say that if anything the standard of the Preliminary Examinations if taken in this way should be raised from 5 to 10 per cent. I would like to propose that a Special Committee be appointed to go into the question of these Preliminary certificates adopting these Bye-laws.

Mr. CARTER: I have very great great pleasure in seconding the motion Mr. Garnett has moved. It is a thing which has my sympathy and support. I am quite

in agreement with everything he has said, and I hope it will meet with the approval of the Council.

Sir JOHN M'FADYEAN: I venture to say, sir, that I think both Mr. Garnett and Mr. Carter must be under a misapprehension, because anyone would gather from what Mr. Garnett said that there are certain examinations at present acceptable by the General Medical Council which we do not accept. I believe that to be not correct. It is also not quite correct to say that it is a rule of universal application that all the subjects of the different examinations must be passed at one time. A clear distinction is drawn in our own schedule and in the Regulations of the General Medical Council in that respect. There is quite a considerable number of examinations included in the list in which the candidate may present himself at different times, that is to say, he may pass part of the examination at one time and part of the examination at another time. In order to obtain universal assent to that statement, I have only to mention that it includes degrees in arts of the various universities at home and in the Colonies, and of course nobody can get a Degree in Arts by sitting at one examination. I rather deprecate the idea that there is at the present time any occasion whatever to throw our regulations with regard to the general knowledge examination so to speak into the melting pot. So far as I know, there is really no reason why we should have Schedule 1 revised at all at the present time, except to eliminate from it certain examinations that may now have become obsolete. When that Schedule 1 was first adopted by us we took it wholesale and verbatim from the Regulations of the General Medical Council, and so far as I am aware we have not altered it since, except to add to it, after due deliberation by this Council, examinations which in the interval had been accepted by the General Medical Council. I do not oppose the proposal that the Committee might also revise the Schedules, but I think it ought not to be suggested to them that they are to consider whether they should strike out any of the examinations in the list unless those examinations are obsolete, and that they should also not consider whether there are any existing examinations to be added to it. If it comes to the knowledge of any member of Council that there is any examination now accepted by the General Medical Council and not accepted by us, the proper procedure is that which has been adopted in several recent cases, to move a resolution in the ordinary course and have the notice of alteration of the Schedule suspended on the notice board. I know a good many other teachers and some of the examiners think that our syllabuses with regard to the various examination subjects might with advantage be reconsidered and perhaps amended, but that is a totally different question. I am not one of those who think that syllabuses are of very great value. I do not think you can tie the hands of an examiner very tightly by a syllabus, but at the same time syllabuses naturally tend to get a little out-of-date, and I would suggest that it might be specifically remitted to the Committee to go into the question of the provision of syllabuses, empowering them to consult with the teachers of the various subjects in the different schools, even if they are not members of Council, and to consult with the present examiners and to bring up recommendations.

Mr. GARNETT: May I be allowed one word of explanation in reply to Sir John? I was referring to those certificates more especially which you will find under Schedule 3 on page 81 of the Register—"Examinations for First Class Certificate (the required subjects to be passed at one or not more than two examinations). Preliminary Examination for medical students (the required subjects to be passed at one time)." According to that the Preliminary Examination for medical students can be passed at more than one examination.

Sir JOHN M'FADYEAN : Which examination is that ?
Mr. GARNETT : The preliminary examination for medical students.

Sir JOHN M'FADYEAN : That relates to the College of Preceptors only. That is the misapprehension. Mr. Garnett is alluding to the four lines under the head of College of Preceptors on page 81, but that relates to the College of Preceptors, and to the College of Preceptors only.

Mr. GARNETT : Then there is the examination of the Educational Institute of Scotland, which I should think a great proportion of our students take, and there again you find the required subjects have to be passed at one time.

Sir JOHN M'FADYEAN : They must be passed at one time in order to satisfy our own Council.

Mr. GARNETT : That is what I want altered. I want our students to be on exactly the same basis as the medical students, who can pass their Preliminary Examinations at various times.

Sir JOHN M'FADYEAN : Excuse me speaking again, sir. I submit, with due respect, that Mr. Garnett is under a misapprehension. If the Schedule were altered as he suggests we would then be making it easier for our intending students than for intending medical students. It is a mistake to suppose that an intending medical student can get an acceptable certificate from the Educational Institute of Scotland without having passed in all the specified subjects at one time. I affirm that to be correct without any shadow of doubt.

Mr. TRIGGER : I would like to say one word with regard to this. It appears to me that if you carry this suggestion to its logical conclusion and have piece-meal examinations we shall defeat our own bye-law. Why on earth then should not the students pass the professional examinations piece-meal ? Our bye-laws are very clear on that point, that that shall not be done now. We insist upon all the subjects being passed at one time. If you pass Mr. Garnett's resolution it will only be necessary to go a step further to open the door towards whitening down the professional examinations as well.

Mr. McKINNA : I am not in favour of Mr. Garnett's proposal. We have got the power in our own hands to lay down the examinations which we accept without copying very much from others. If we adopt the suggestion we shall lower our standard rather than raise it.

The PRESIDENT : I take it the Council are of opinion generally that these schedules should be passed in review, and that the Committee will have to report this Council before anything can be done. No harm will be done in reviewing the schedule of educational certificates. I think the speakers generally have been of opinion that the schedule should be passed in review, and it has been suggested that certificates might be deleted if they are obsolete.

Mr. ARSON : I remember some years ago this subject came up and was discussed for some considerable time by the Council, and after a sharp fight we came to the unanimous conclusion that the Matriculation examination should be passed at one time. I see no reason whatever why that should be altered now.

The PRESIDENT : This is really a matter for future discussion ; it does not really arise under this report. It has been suggested that the two schedules should be sent to the Examination Committee for revision, and then their report can be discussed subsequently. The question of any alteration should not come up now.

Mr. TRIGGER : I do not think there is need for any revision at the present time, and I move an amendment that we do not consider the matter.

Mr. MASON : I second that.

The PRESIDENT : That will be an amendment to Mr. Garnett's resolution, and it will be in the form I pre-

sume that no action be taken as regards this Education Schedule.

The amendment was then put and carried, 8 voting for and 5 against.

The PRESIDENT : I take it it is the feeling of the Council that in that revision of the bye-laws the schedule referring to the professional examinations be considered by the Examination Committee. You referred to that, Sir John in your speech.

The TRIGGER : But my amendment has been passed.

The PRESIDENT : I quite understand that, but that applies to the education. Sir John spoke with regard to the professional examination syllabuses.

Sir JOHN M'FADYEAN : I suggest it should be considered by the same Committee which has been appointed.

The PRESIDENT : That they shall have the power to pass in review the syllabuses of the professional examination.

Sir JOHN M'FADYEAN : The motion is Mr. Garnett's. The PRESIDENT : That referred, I take it, to the Educational certificates.

Sir JOHN M'FADYEAN : No, to the whole of the schedules.

The PRESIDENT : But the amendment which I put and which was carried was with regard to the Educational certificates.

Sir JOHN M'FADYEAN : Yes, and in so far as Mr. Garnett's motion related to the Educational certificates it is defeated.

The PRESIDENT : Will somebody propose, in order to clear the deck, that the syllabuses of the professional examinations be considered by this Committee ?

Mr. McKINNA : There is already a Committee in existence.

The PRESIDENT : There is no reference to them. Mr. McKINNA : Why should not the Committee continue its labours until it finishes ?

Prof. BRADLEY : I move that the Second Schedule be referred back to the same Committee.

Mr. BANHAM : I second that.

The PRESIDENT : It is proposed by Prof. Bradley, and seconded by Mr. Banham, that the syllabuses of the professional examinations be referred to the Committee, with power to obtain information from examiners and teachers.

The resolution was then put and carried.

Mr. VILLAR : I should like the position to be made quite clear. Is the Examination Committee to consider Schedule No. 1 ?

The PRESIDENT : No, Schedule No. 2.

Mr. VILLAR : Mr. Garnett's motion that a Special Committee should be appointed was defeated ?

The PRESIDENT : Yes. What has been passed now is that we refer back to the Examination Committee the facts relating to the professional examinations, Schedule No. 2.

Mr. VILLAR : And on Schedule No. 1 no action ?

The PRESIDENT : Yes.

The resolution for the adoption of the report of the Examination Committee was then put and carried unanimously.

PARLIAMENTARY COMMITTEE.

Mr. GARNETT read the following report of a meeting of the Parliamentary Committee held on October 12th, 1911 :—

Appointment of Chairman.—It was resolved that Mr. F. W. Garnett be appointed Chairman of this Committee for the ensuing year.

Minutes.—The minutes of the meeting held on April 6th having been printed and circulated, were taken as read and confirmed.

Informal Meeting.—The following report of an in-

formal meeting, held on July 7th, was read and confirmed:—

Finance Bill.—The Chairman explained that the meeting was called in order to discuss a matter which had arisen since the issue of notices convening Committee meetings.

A letter was read stating that a petition was being laid before the Chancellor of the Exchequer with the view to obtaining an exemption from the special licence required for the sale of alcohol to medical practitioners and pharmacists, and suggesting that an attempt should be made to obtain the same exemption in favour of veterinary surgeons.

It was resolved that the matter be left in the hands of Mr. W. F. Barrett.

It was resolved that a petition be lodged with the Chancellor of the Exchequer praying that veterinary surgeons be placed on the same footing as medical practitioners and pharmacists with regard to the purchase of small quantities of alcohol.

Protection of Animals Act.—The Chairman reported the passing into law of the Protection of Animals Act, 1911.

And it was resolved that the Clauses of this Act relating to veterinary surgeons be published in the Register for 1912.

General Purposes: Cleaning of Windows.—Estimates were submitted for the cleaning of the windows in the College building, and the estimate of the Army and Navy Cleaning and General Industries Co., Ltd., was accepted.

Mr. GARNETT: I move that the minutes be received and adopted.

Mr. ROBERTS: I second that.

Mr. TRIGGER: Have you the assurance that these men are all insured by the companies?

Mr. GARNETT: Yes, that is so.

The resolution for the adoption of the report was carried unanimously.

ANNUAL FEE COMMITTEE.

Sir JOHN M'FADYEAN read the following report of a meeting of the Annual Fee Committee held on October 12th, 1911:—

Appointment of Chairman.—It was resolved that Sir John M'Fadyean be appointed Chairman of this Committee for the ensuing year.

Minutes.—The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Amendment Bill.—The Committee had again under consideration the following resolutions from the Highland Agricultural Society:—

COPY OF RESOLUTIONS ADOPTED UNANIMOUSLY AT A GENERAL MEETING OF THE MEMBERS OF THE HIGHLAND AND AGRICULTURAL SOCIETY OF SCOTLAND, HELD 7TH JUNE, 1911.

Veterinary Surgeons Act (1881) Amendment Bill.—

1. That the Society learns with satisfaction that the Sections of the Bill providing for the extension of the disciplinary powers of the College have been withdrawn.

2. That the Society would desire to refrain from taking action with regard to the domestic policy of the College or of the profession, provided the interests of stockowners were reasonably safeguarded, and therefore would be prepared to withdraw its opposition if Sub-section 5, Section 3, be amended so as to provide that such bye-laws as may be made or altered under the provisions of this Sub-section must have the approval not only of the Privy Council but also of the Board of Agriculture and Fisheries.

The Solicitor reported that he had had further correspondence with the Secretary of the Society, but that he

had been unable to induce the Society to alter their attitude on the point raised, namely that the bye-laws to be made under the new Act should be submitted to the Board of Agriculture as well as to the Privy Council. The Committee recommend that no further action be taken in the matter at present.

It was resolved that the Veterinary Surgeons Act (Amendment) Bill be reintroduced in the next session of Parliament.

It was also resolved to recommend that the name of Dr. Bradley be added to the list of Members of the Committee.

On the motion of Sir John Fadyean, seconded by Mr. Trigger, the report was adopted.

PUBLICATION COMMITTEE.

Mr. ABSON read the following report of a meeting of the Publication Committee held on October 13th, 1911:—

Appointment of Chairman.—It was resolved, (a) That Mr. Stockman be appointed Chairman of this Committee for the ensuing year.

(b) That in the absence of Mr. Stockman the Chair be taken by Mr. J. Abson.

Minutes.—The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Register, 1912.—The printing of the Register for 1912 was considered, and it was resolved that the work be entrusted to Messrs. H. & W. Brown, and that 500 copies be printed.

Advertisements.—The Secretary was instructed to continue the insertion of advertisements and to endeavour to obtain a larger number.

On the motion of Mr. Abson, seconded by Mr. Mulvey, the report was received and adopted.

STEEL MEMORIAL COMMITTEE.

The SECRETARY read the following report of a meeting of the Steel Memorial Committee held on October 13th, 1911:—

Appointment of Chairman.—It was resolved that Prof. A. E. Mettam be appointed to the Chair.

Minutes.—The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Award of Steel Medal.—The question of the award of the Steel Medal was considered, and, after discussion, it was resolved to recommend that the medal be not awarded this year.

On the motion of Mr. Mason, seconded by Mr. Mulvey, the report was received and adopted.

FITZWYGRAM PRIZE FUND.

The SECRETARY read the report of the Auditors on the FitzWygram Prize Award, which certified that they had checked and found correct the number of marks gained by the students shown on the list, the first two being Mr. J. T. Edwards, of the Royal Veterinary College, London, 820 marks, and W. D. Connochie, of the Royal Dick College, Edinburgh, 818 marks. The total income to be divided was £63 18s. 4d. The first prize, which, in accordance with the Trust, was five-eighths of the amount, was £39 18s. 11d., and the second prize, consisting of the remaining three-eighths, was £23 19s. 5d.

Mr. VILLAR: I beg to move that the report of the Auditors be accepted, and that cheques be drawn for the amounts and forwarded to the successful candidates. It is quite interesting to note the severe competition there has been between the winners of the prizes. You will notice that on a total of between 800 and 900 marks there is a difference of only two between the first and second.

Mr. LAWSON seconded the motion, which was carried unanimously.

WALLEY MEMORIAL PRIZE AWARD.

The SECRETARY: I have to report that I have received a letter from Mr. Woods saying, "I cannot let you have the result to-morrow; I have not yet received the report of the Examiners." The result must therefore be deferred until January. It is rather early to expect the result at this meeting. It has usually been announced in January.

Sir JOHN M'FADYEAN: You must remember the examination was only held on September 30th.

APPOINTMENT OF SECRETARIES OF BOARD OF EXAMINERS IN SCOTLAND, LIVERPOOL, AND DUBLIN.

The PRESIDENT: Applications have been received from our old local secretaries, Mr. Archibald Baird in Edinburgh, Mr. Finlay Kerr in Dublin, and Mr. Blackhurst in Liverpool. There are no other applications for the posts.

Sir JOHN M'FADYEAN: I beg to move that these gentlemen be respectively appointed Secretaries of the Board of Examiners in Edinburgh, Dublin, and Liverpool for another year.

Mr. MASON: I second that.

Mr. CARTER: May I ask what is the salary awarded to Mr. Blackhurst of Liverpool?

The SECRETARY: Ten guineas per annum.

Mr. CARTER: Mr. Blackhurst asked me if I would kindly ask the Council if they would grant him a little additional amount above that. I am quite aware of the strained condition of the finances of the College, but I think you should bear in mind that Mr. Blackhurst has to devote the whole of ten days to this work, and I believe I am correct in saying that he has to pay his railway fares and cab fares out of the ten guineas paid him. If the College could see its way even to pay the fares it would be something, because you cannot expect Mr. Blackhurst to carry a big bag across the town at the time of the examination. He is bound to have a cab.

Mr. TRIGGER: I rise to a point of order. There is no application for an increase of salary.

Mr. CARTER: I believe he has mentioned it in his letter.

Mr. MULVEY: He has not made an application for an increase, although he has protested against the smallness of the amount paid.

The PRESIDENT: I will read his letter. He says: "If it meets with the wishes of the Council I shall be pleased to act again as the Secretary for Liverpool, although the fee is very small for such a responsible position.—Faithfully yours, Charles Blackhurst."

Mr. CARTER: If this Council could see its way I should like them to increase the amount they pay to him.

The PRESIDENT: It has been proposed that these three gentlemen be re-elected as Local Secretaries. Is that your wish?

The resolution was carried unanimously.

NOTICE OF MOTION.

Mr. VILLAR: I have to give notice that at the next meeting of this Council I shall propose, in my capacity as Chairman of the Examination Committee, the alteration of some of the bye-laws referring to the examinations. These have already been considered by the Examination Committee, and the list of alterations will be suspended according to the terms of our Charter.

VOTE OF THANKS TO THE PRESIDENT.

Mr. MASON: I should like to move a vote of thanks to the President for the expeditious manner in which he had despatched the business to-day.

Mr. McKINNA seconded the motion, which was carried by acclamation.

The PRESIDENT having briefly acknowledged the compliment, the meeting terminated.

SOUTHERN COUNTIES
VETERINARY SOCIETY.

(Continued from p. 238.)

VISIT TO ARMY VETERINARY SCHOOL, ALDERSHOT.

On the conclusion of the meeting, the members and visitors, under the guidance of Major Newsom, proceeded via Gun Hill to the School, where they were received by Col. E. H. Hazelton, F.V.O., Aldershot Command, and other officers present were Capt. E. P. Argyle, Capt. E. J. Wadley, Capt. Steevenson, with Messrs. B. R. Body and F. Sheedy.

The X-ray apparatus, as the first installation of its kind in England, and as being regarded yet as quite a luxury by the general run of private practitioners, claimed first attention. It is housed in a building about 40ft. square: a standard 8ft. high carries a horizontal arm by a clamp adjustment, and having a long pitched screw adjustment horizontally, so that the bulb can be brought into action from the near fetlock to the off ear of a tall troop horse. The bulb is carried in a blue glass globular screen open at the back with a two-inch aperture for exposure. The plates are carried in envelopes impervious to daylight. The current is taken from the service mains at 200 volts, and is reinforced by the use of a "booster"—a large induction coil—which enables the time of exposure to be reduced to one-sixth of a second—a valuable consideration in the case of a fidgety animal. Major Newsom very kindly had a couple of horses brought in, and with the aid of a junior officer gave a demonstration of the apparatus in use.

Then the class room was visited, with seating and desk room for about 30 men. This is used for the elementary teaching of the men of the Corps as well as for officers in training, and has amongst patterns of shoes, specimens of grasses, and other appliances, a 3ft. folding anatomical model of a horse.

The laboratory runs across the building, and so is lighted from both ends. There is room for five microscopes, with the usual tiled bench with tube rack, and necessary fittings. At the other end are sinks, an electric centrifuge, a rapid water heater, and other conveniences. Altogether the impression to a visitor was that it is a compact, serviceable, workmanlike outfit. An item that attracted attention from several members who belong to the Territorial Force was a tattooing process, which replaces the old practice of branding on the hoof. It is applied on the membranes over the upper incisors, and is likely to be generally used. Incidentally it was mentioned that there were over 7000 horses in and about the camp.

The museum is on the floor above, and as might be anticipated, contains a large collection of bones. There is a variety of specimens of shoes and saddlery, drugs and foods, and a model of the enclosures for exercising horses, devised by Major F. Eassie, and successfully used at the remount depôts in the South African war. Many other objects of interest had to be passed without examination—time did not allow of it.

A very pleasing feature of the visit was the readiness of all, seniors and juniors alike, to explain in reply to the numerous enquiries, and generally to make the visit a pleasant one.

Tea was provided in the Library by the kindness of Colonel Hazelton and his staff, and before leaving,

Mr. SLOCOCK, as the senior Vice-President, said that he was sure it was the wish of every member of their party that day that they should tender their hearty thanks to Colonel Hazelton, Major Newsom, and the other officers of the staff for their kindness and courtesy in entertaining them that afternoon. They had enjoyed an intellectual feast as well as bodily refreshment, and he was sure he was expressing the sentiments of them

all when he said they hoped they would have the pleasure of paying another visit when they met in Aldershot again. (Applause.)

Colonel HAZELTON, in reply, said it was very kind of Mr. Slocock to thank his brother officers and himself for the little they had done, and he could only say it had given them quite as much pleasure to receive them as they had experienced in coming to see the School. The School was a place which they thought the members of the Society would like to see, and Major Newsom was a most enthusiastic and interesting guide, in fact he liked to lecture and talk so much that he (Colonel Hazelton) did not often go near him more than he could help. (Laughter.) He was sure, however, it had given a real pleasure to the Major to go round the School with them that day, and when they did come to Aldershot again he hoped they would also come and see them again. (Applause.)

J. ALEX. TODD, *Hon. Sec.*

VICTORIA VETERINARY BENEVOLENT FUND.

The quarterly meeting of the Council of this Fund was held at 10, Red Lion Square, Holborn, on Thursday, October 12th. There were present Mr. P. J. Simpson in the Chair (owing to the absence of the President in South Africa), Messrs. Trigger, Villar, MacCormack, Hobday, Dunstan, Garnett, Gooch, Banham, Abson, Burt, junr., Slocock, Prof. Woodruff, and the Secretary, W. Shipley.

The minutes of the previous meeting having been read and confirmed,

The SECRETARY reported that further enquiries and investigations had been made as to the position of the recipients of the grants. It was felt that great efforts should be made to increase the number of annual subscribers, and with the hope of that object being attained, increased grants were made in the most deserving cases.

There were three fresh applications for relief. Grants were made in two cases, and further enquiries to be made in the third. Only the financial position of the Fund prevented larger grants being made.

It was resolved to appoint a Finance Committee to assist the Secretary and Treasurer and to advise the Council. The following members were proposed and adopted: Messrs. R. C. Trigger, F. W. Garnett, and P. J. Simpson.

A leaflet stating the objects of the Society, as follows, was adopted.

This Fund was established as a memorial to the late Queen Victoria by the members of the veterinary profession. The objects of the Society are to afford assistance to necessitous and deserving members of the Royal College of Veterinary Surgeons, or necessitous members of the families of members of the Royal College of Veterinary Surgeons.

There are many claims on the Funds of the Society with only a limited income to meet them. Our income from subscribers is considerably less than our expenditure.

Help in the way of annual subscriptions is urgently needed.

The members of the Council will welcome any information from members of the profession as to cases of distress for investigation, as they are aware many sad cases exist which never come to their knowledge.

Your assistance as an annual subscriber is earnestly solicited.

Any particulars can be obtained on application to the Honorary Secretary, Mr. W. SHIPLEY, F.R.C.V.S.

It is hoped the members of the Council and others interested will obtain a supply of these leaflets from the Secretary for distribution among their friends.

The banking account of the Fund was transferred to Messrs. Barclay and Co., Great Yarmouth, for the convenience of the Treasurer.

W. SHIPLEY, *Hon. Sec.*
28 Southtown, Gt. Yarmouth.

THE CENTRAL VETERINARY SOCIETY.

The annual general meeting was held at 10 Red Lion Square, W.C., on Thursday evening, October 5th. Mr. W. S. Mulvey, President, occupied the chair, and the following Fellows signed the attendance book: Messrs. R. J. Foreman, A. E. Willett, P. W. Dayer Smith, Sydney H. Slocock, W. Perryman, James Rowe, E. Lionel Stroud, H. D. Jones, James A. Gosling, A. Rogerson, W. Roger Clarke, and Hugh A. MacCormack, *Hon. Sec.*

On the motion of Mr. Foreman, seconded by Mr. Rowe, the minutes of the last meeting were taken as read and confirmed.

CORRESPONDENCE.

The SECRETARY announced that letters regretting their inability to attend the meeting had been received from Messrs. J. C. Coleman, J. W. McIntosh, and Charles Roberts.

The following letter from Prof. A. Gorton, *Hon. Sec.* of the proposed Amalgamation of Veterinary Associations, was read:

"Royal (Dick) Veterinary College,
Edinburgh, Sept. 4, 1911.

Dear Sir,

I have to intimate that the following resolution was carried at the annual meeting of the National Veterinary Association: "That the rules of the National Veterinary Association as amended by the Committee appointed for the purpose and submitted at the meeting of the Council at Carnarvon on July 25th, be adopted, and that the same Committee be reappointed to make arrangements to bring the amended rules into operation at the annual meeting of the Association to be held in 1913."

A further motion was submitted and carried whereby it was ensured that existing members of the National Association shall become members under the amended rules.

I should be glad if you would intimate these resolutions to your Society at its first meeting, and as your Society has already expressed approval of the scheme, I should be glad to hear from you that it has formally expressed its intention of becoming affiliated to the National Association in accordance with the new rules.

—Yours truly,

(Signed) A. GORTON,
Hon. Sec. of the Committee.

The PRESIDENT moved that the subject should be put down for discussion on the agenda of the December meeting.

Mr. SLOCOCK seconded the motion. The matter, in his opinion, was one of considerable importance, which every Fellow of the Society should have the chance of enquiring into.

The resolution was carried unanimously.

RESIGNATIONS.

The SECRETARY announced that letters had been received from the following gentlemen tendering their resignations as Fellows of the Society: Major-General Sir Frederick Duck, K.C.B., Lieut.-Col. Longhurst, Mr.

Alfred Prudames, Mr. Ainsworth Wilson, and Mr. J. B. Hare.

The PRESIDENT thought that as Mr. Ainsworth Wilson was such an old Fellow of the Society and an old member of the Council, it would be very desirable that the Secretary should write to him and ask him not to resign, though he be living in Scotland.

Mr. FOREMAN suggested that the same course of procedure should be adopted with regard to Mr. Hare, who had removed to a town not very far from Dublin.

Mr. SROUD thought that as Mr. Prudames was an old past President and a very old Fellow of the Society, his resignation should not be accepted in the ordinary way. He suggested that the Secretary should specially write to Mr. Prudames expressing the Society's very great regret that old age had compelled him to sever his connection with it. It was simply through old age that Mr. Prudames had resigned, and old age makes many partings.

Mr. ROWE heartily supported Mr. Stroud's suggestion.

It was then unanimously agreed that the Secretary should write letters to Mr. Ainsworth Wilson, Mr. J. B. Hare, and Mr. A. Prudames in accordance with the suggestions made; and on the motion of Mr. Dayer-Smith, seconded by Mr. A. E. Willett, it was resolved that the resignations of Major-General Sir Frederick Duck and Lieut.-Col. Longhurst should be accepted with regret.

ELECTION AND NOMINATIONS.

Mr. R. STOKOE, M.R.C.V.S., London Road, Chelmsford, was balloted for and unanimously elected a Fellow of the Society.

Messrs. GEORGE GORDON, Victoria Road, N.E.; FRANK MACDONALD, Mile End Road; and J. D. WOOD, Public Health Department, L.C.C., were nominated as Fellows of the Society.

ANNUAL REPORT.

The SECRETARY read the following annual report:

Mr. President and gentlemen,—The Council have great pleasure in announcing that the Session 1910-11 has been a very successful one.

Nine Fellows have been elected and six have resigned. The annual meeting was held in October, at which Mr. W. S. Mulvey was unanimously elected President. Ten ordinary, one special Council, and two Council meetings have been held with an average attendance of thirty at the ordinary meetings.

In November the annual dinner was held at the Holborn Restaurant, at which 43 were present. At the December meeting the President gave his address.

We have to thank the following gentlemen for reading papers during the session: Mr. W. Hunting, "Questions concerning quittor"; Prof. H. A. Woodruff, "Our knowledge of the cause of roaring"; Mr. J. W. McIntosh, "Anthrax—its practical aspect"; W. R. Bennett, "Mange in horses"; Mr. W. Hunting, "Some questions concerning spavin."

Three meetings were devoted to impromptu discussion and reporting of difficult cases: the discussions therefrom were very instructive.

Mr. T. Salusbury Price delivered his report of the Public Health Congress held at Birkenhead, also Mr. G. H. Livesey his report of the Royal Sanitary Institute Congress held at Brighton this year. Mr. G. J. Bell represented the Society at the Royal Sanitary Institute Congress, Dublin; Messrs. A. L. Butters and J. J. Kelly were appointed to represent the Society at the Public Health Congress, Belfast, and their reports will be given in due course.

Your Council are gratified to note the increased number of interesting and instructive specimens brought forward at the meetings, and they hope Fellows will continue doing so. We beg to thank the following Fellows: Messrs. W. S. Mulvey, Prof. G. H. Wooldridge,

F. G. Samson, Prof. J. Macqueen, T. Salusbury Price, Prof. H. A. Woodruff, G. H. Livesey, W. Urquhart, J. W. McIntosh, S. H. Slocock, W. R. Davis, H. D. Jones, and W. Perryman.

The balance brought forward and receipts for the year amounted to £129 1s. 9d., and the expenses £78 13s. 1d. leaving a balance of £50 8s. 8d., which the Council consider satisfactory.

On the motion of Mr. A. E. Willett, seconded by Mr. Perryman, the report was unanimously adopted.

BALANCE SHEET.

The HON. TREASURER (Mr. Stroud) presented the balance sheet. In doing so, he said it would be noticed that the subscriptions were considerably less than last year. There was also a greater number of arrears to collect, between £50 and £60 being now owing to the Society from last year's and previous years' subscriptions. The balance itself was not quite so large as in the previous year, but ten guineas had been transferred to capital account, otherwise the balance would have been slightly larger than in the previous year. The other figures in the balance sheet were the ordinary figures that were published every year, and he did not think they called for any special comment.

Mr. ROGERSON, in proposing that the balance sheet be adopted, thought that the accounts, which had been duly audited, were a great credit to the Society. There was a nice balance in hand, and taking everything into consideration, the Society seemed to be in a fairly prosperous condition.

Mr. J. A. GOSLING seconded the motion, which was carried unanimously.

On the motion of Mr. Perryman, seconded by Mr. Jones, it was unanimously resolved that the Hon. Secretary and Hon. Treasurer should act as Scrutineers of the ballot for the election of President and officers.

ELECTION OF OFFICERS.

President.—The PRESIDENT considered he was greatly privileged in being able to nominate his successor in Mr. Foreman. (Cheers.) Mr. Foreman was one of the oldest Fellows of the Society, and had served on the Council rather longer than most of the preceding Presidents. There was no necessity for him to eulogise Mr. Foreman's qualifications for the position, because the Fellows knew quite as much about him as he did. He had the greatest possible pleasure in proposing that Mr. Foreman be elected President for the ensuing year. (Cheers.)

Mr. BUTTERS, in seconding the motion, said that everyone who had regularly attended the meetings knew the active share Mr. Foreman had taken in all the affairs of the Society, and if Mr. Foreman was willing to accept the Presidency he was sure the Society could not do better than elect him to that honourable position. (Cheers.)

The resolution was then put, and carried with acclamation.

The RETIRING PRESIDENT (Mr. W. S. Mulvey), before vacating the Chair, desired to thank the Fellows for the very great courtesy and kindness they had extended to him during the past year. His year of office had been a very easy and a very pleasant one, and if the Fellows were satisfied with his conduct of the affairs, the memory of it would be still more pleasant to him. (Cheers.)

The Chair was then vacated by Mr. Mulvey, and taken, amid hearty cheering, by Mr. Foreman.

The PRESIDENT (Mr. Foreman), who was received with cheers, thanked the Fellows for electing him President, and assured them that he greatly esteemed the honour which had been conferred upon him as he had great respect for the dignity of the Chair. If at any time during his term of office he had, should he say, to

be "objectionable" to any Fellow for breach of rules, it would not be as a private individual, but as the President trying to uphold the traditions of the Chair; and he hoped his ruling would be accepted in a like spirit. (Hear, hear.) He had said "if" only, and hoped that his term of office would be as free from any such necessity as the previous ones had been. He desired to ask the Fellows to offer papers for discussion. He especially asked them not to be afraid of offering too many. The Secretary would not be non-plussed even at such an extraordinary occurrence. (Laughter.) He would very much like to see Mr. MacCormack embarrassed in that way. He suggested that the Fellows who had recently joined should drop their bashfulness and enter freely into the discussions, as he was certain they could. Perhaps they feared criticism from the senior Fellows! Well, criticism was not harmful to health, and if they did get a bit of a knock it would not cause death through "shock to pride." They would just "chew" it over with a few cronies after the meetings, and would then find themselves laughing over the experience. (Laughter, and hear, hear.) He had been through the experience, so that he spoke with authority. He hoped the senior Fellows would continue to keep up the discussions and eliminate those awful pauses which made a President squirm. (Laughter.) He had intended to give a growl or two about the Fellows coming late to meetings, and also about holding conversations during the reading of the papers, but he would not do so on the present occasion for fear of getting himself disliked before being really sampled as President. (Laughter.) He now had the greatest pleasure in asking the Fellows to give a very cordial vote of thanks to Mr. Mulvey, the past President, for fulfilling the office so ably during the last session. To follow an experienced gentleman like Mr. Price was difficult, but he had managed it so well, with the assistance of the Fellows, that he hoped they would help him in a like manner to a successful year of office. (Cheers.)

Mr. A. E. WILLETT, in seconding the motion, said that Mr. Mulvey had always conducted the business of the Society in such an excellent manner that the Fellows had greatly enjoyed the meetings during the past year.

The resolution having been carried by acclamation,

Mr. W. S. MULVEY thanked the mover and seconder for the very kind things they had said about him, and the Fellows for the hearty manner in which they had received them. His year of office had been a very pleasant one, and now he had been assured that the Fellows were satisfied with his conduct of the business the memory of it would be still more pleasant to him.

Vice-Presidents.—The following gentlemen were elected: Messrs. W. S. Mulvey, A. Rogerson, J. A. Gosling, and P. W. Dayer-Smith were elected for the ensuing year.

Hon. Secretary and Hon. Treasurer.—Mr. MULVEY, in moving that the present Hon. Secretary and Hon. Treasurer be re-elected, said that Mr. MacCormack and Mr. Stroud had acted for so many years in their respective capacities that he was sure the Society could not find more desirable officials, because their work had always been done excellently. (Cheers.)

Mr. ROWE, in seconding the motion, heartily endorsed the sentiments of the proposer of the motion.

The motion was put and carried with acclamation.

The HON. TREASURER (Mr. Stroud), in returning thanks for the further honour conferred upon him, said that next February he would have completed twelve years of office in the Society, and it afforded him great pleasure to know that after so many years of work he still retained the confidence of the Fellows. (Cheers.)

The HON. SECRETARY (Mr. MacCormack) also thanked the Fellows for the great confidence they had shown in him by electing him for another period of office. He

had not been so long in office as Mr. Stroud, but he ran that gentleman fairly close. He was afraid, however, the fellows would have to look out for a new Secretary next year. (Cries of "No, no.") He was getting old—(laughter)—and the Fellows did not answer his "whip" so readily as they did in previous years. There was nothing like new blood for successfully carrying out the duties of the Secretaryship of such an important Society.

The PRESIDENT asked the members not to take too much notice of Mr. MacCormack's pessimistic remarks. Unfortunately the Hon. Secretary was not very well, and really ought to be at home in bed instead of at the meeting. At any rate, the Fellows would not accept his little tale of woe at present. (Hear, hear.)

Council.—The following gentlemen were elected:—Messrs. A. L. Butters, Prof. J. Macqueen, W. Perryman, Sydney H. Slocock, J. Willett, W. L. Harrison, Sidney Villar, J. W. McIntosh, Wm. Hunting, Prof. G. H. Woodriddle, Prof. H. A. Woodruff, and J. Rowe.

Auditors.—The PRESIDENT reminded the Fellows that two Auditors had to be elected, one of whom must be a member of the Council and the other a Fellow of the Society.

On the motion of Mr. Mulvey, seconded by Mr. Rogerson, the retiring auditors, Mr. Dayer-Smith and Mr. Roger Clarke were unanimously re-elected.

Dinner Committee.—It was unanimously resolved that the President, the Hon. Treasurer, the Hon. Secretary, Mr. Rogerson, and Mr. Hunting should form the Dinner Committee.

On the motion of Mr. Slocock, a hearty vote of thanks was accorded to the President for his conduct in the Chair, and the meeting terminated.

HUGH A. MACCORMACK, Hon. Sec.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION

A meeting was held in the Imperial Hotel, Darlington, on Friday, June 9. Mr. G. R. Dudgeon, President, in the chair. There were also present: Messrs. Dobbing, Taylor, and Hill, Darlington; W. H. Blackburn, Barnard Castle; John Wilson, Yarm; E. H. Pratt, Northallerton; and W. Awde, Hon. Sec., Stockton-on-Tees.

Mr. Snaith sent a telegram expressing his inability to be present. Mr. Jenkins also sent an apology.

The minutes of the previous meeting were taken as read and confirmed, on the proposition of Mr. Taylor, seconded by Mr. Hill.

Mr. HILL produced a freak of nature, viz., a leg from a cart foal which had the splint bone extra developed, with an appendage like a rudimentary limb.

Mr. BLACKBURN had met with a similar case and the foal was insured. The insurance company, however, demurred to pay for it if it was destroyed.

Mr. HILL also mentioned a case of parturition in which the tail was presented and he effected delivery with a hook in the pelvic bone and one over the crupper.

Mr. WILSON had met with one or two cases similar to that of Mr. Hill.

NOTES ON AN OUTBREAK OF ANTHRAX.

Mr. E. H. PRATT.

I think the following notes on an outbreak of anthrax to be of interest to the profession.

On Sunday, July 10th, a feeding bullock was found ill in the pasture. The services of a butcher were secured and the animal was bled where it lay: no precautions were taken to keep the other bullocks away (there were

eighteen of them). After the beast had been bled it was dragged on a gate to a barn and there dressed.

The butcher noticed that the spleen was enlarged, and as he had scratched his hand in getting over a fence on his way to the field where the beast was, he began to think about anthrax, and in the evening went in to Thirsk to see Mr. Wood, M.R.C.V.S., to get some information about the disease. Mr. Wood confirmed his doubts, and next day was called by the owner to see the carcass. He was able to confirm his diagnosis by microscopical examination of the blood and the case was reported to the police.

I visited the farm with Mr. Wood and found at the place where the beast had been bled the grass all trodden down by the other beasts. It was reported that some of them had licked up the spilt blood. The carcass was cremated and the contaminated sods taken up and burnt.

Nothing was noticed amiss with any of the other animals until Monday morning, the 18th, when, as the seven days had elapsed which the Anthrax Order specifies contact animals shall be isolated, the owner intended to send some which were fat to the mart. Five, however, were noticed to be ailing, and the fact was reported to the police and none of the animals were removed. One of the five died by noon, one in the evening, and one during the night: the fourth died on Tuesday night the 19th, and the remaining one died on Saturday the 23rd, five days after first being noticed to be ill.

One is of opinion that the five animals which died from the 18th to the 23rd contracted the disease through getting some of the blood from the animal which was bled in the field. It therefore gives one a lesson in the time of incubation, and also shows that the disease does not always run such a rapid course as is very generally supposed.

The PRESIDENT then broached the subject of a "picnic" and thought it could be made a success if well managed. After considerable discussion Mr. Taylor proposed, and Mr. Wilson seconded, that a picnic be held, and a provisional Committee be formed to take the matter in hand and make the necessary arrangements forthwith: Messrs. Dobbing, Hill, and Taylor to form the Committee.

Mr. HILL opened the discussion on the President's address (p. 761, June 3), and thought that we should come to some arrangement and fix a minimum charge for operations, mileage, etc. He had been asked to go to a place three miles away to castrate a colt, and when he had arrived the owner asked what he was going to charge for operation, and when told, flatly declined to have him done at the price.

Mr. WILSON thought that the Insurance companies were beginning to offer better terms for the examination of animals, but there was still room for improvement.

Mr. TAYLOR considered that castration fees should be higher than they now are, but considerable difficulty would be experienced in raising them as there were men who still take the old price. The payment of a guinea registration fee was quite right in his opinion as it would go to the benefit of the profession.

Mr. PRATT thought a meeting of members and non-members might be called, and the question of fees could be discussed openly, and they might bind themselves to some joint action.

Mr. BLACKBURN said that he had been offered 3s. after operating on a colt. He also mentioned the fees paid by the Board of Agriculture for examining mares, viz., 7/6, and did not consider that it was sufficient. The difficulty is to get members to combine, and so many belong to no veterinary association.

Mr. DOBBING thought we ought to stand by each other and make uniform charges and stick to them.

The SECRETARY had found great difficulty in obtaining concerted action.

Mr. DUDGEON then replied, and said that the opinion generally expressed was that the fees were not satisfactory, but how to get them remedied is the crux of the whole question. The Insurance Companies expect you to make their examinations when passing the places, but considering the nature of the questions asked, and which had to be answered, the fee was far too little. The trouble would be to bind anyone to any arrangement arrived at or agreed to.

Mr. HILL proposed, and Mr. Wilson seconded, that a meeting of members and non-members be called to consider the question of fees, and that it be held four weeks to-day, viz., on July 7th, and that a notice be inserted in *The Veterinary Record*.—Carried.

ELECTION OF OFFICERS.

President.—Mr. W. AWDE, F.R.C.V.S., Stockton-on-Tees. Proposed by Mr. Taylor, seconded by Mr. Dudgeon.

Vice-Presidents.—Mr. C. G. HILL, M.R.C.V.S., Darlington; Mr. J. H. TAYLOR, F.R.C.V.S., Darlington. Proposed by Mr. Dudgeon, seconded by Mr. Wilson.

Secretary and Treasurer.—Mr. J. H. TAYLOR, F.R.C.V.S., Darlington. Proposed by Mr. Awde, seconded by Mr. Hill.

Auditors.—Mr. W. N. DOBBING, M.R.C.V.S., Darlington; Mr. J. H. TAYLOR, F.R.C.V.S., Darlington. Mr. W. Awde proposed their re-election, and Mr. Wilson seconded.

It was proposed that Mr. Hill's paper and discussion thereon be adjourned till another meeting.

W. AWDE, Hon. Sec.

A meeting was held in the Imperial Hotel, Darlington, on Friday, Oct. 6th. The retiring President, Mr. G. R. Dudgeon, Sunderland, being in the Chair. There were also present Messrs. P. Snaith and A. C. Forbes, Bishop Auckland; W. H. Blackburn, Barnard Castle; J. Wilson, Yarm; W. N. Dobbing, C. G. Hill, and J. H. Taylor, Darlington.

The minutes of the June meeting not being to hand, those of the special meeting held on July 7th were taken as read, on the proposition of Mr. Snaith, seconded by Mr. Wilson.

Mr. J. M. WALKER, West Hartlepool, was unanimously elected a member, on the proposition of Mr. Hill, seconded by Mr. Forbes.

A letter was read from Mr. W. Awde, the President-elect, regretting very much that he was unable to be present owing to illness, and apologies for non-attendance were also received from Messrs. H. Peele, E. H. Pratt, J. M. Walker, and F. H. Jenkins.

Mr. Jenkins wrote stating that he thought the report upon a roarer operated upon by Prof. Hobday on June 20th last might interest the members. The subject was a bay hunter, six years old, 17 h.h., a very bad roarer indeed which could be heard a good distance away, the operation was performed on both sides of the larynx. For the last month or six weeks the horse had been gently trotted and cantered, and no noise detected.

On October 3rd he had given the horse a very trying test, and was unable to detect the slightest noise, and had he not known of the operation he should not have had the slightest suspicion that it had taken place, the external wound having healed so well.

The Hon. Sec. was instructed to write and thank Mr. Jenkins for his letter.

A letter was read from Prof. Gofton re joining the National Association in accordance with the amalgamation scheme, and it was unanimously agreed on the proposition of Mr. Snaith, seconded by Mr. Forbes, that

this Association become affiliated to the National Association in accordance with the new rules.

A letter was read from Prof. Woodruff *re* the fund for the purpose of assisting Mr. William Kirk in the appeal raised by the London County Council to compel veterinary surgeons to pay for the use of the College crest.

A discussion took place as to whether the Association should subscribe a certain sum, or whether it should be left to the individual members to contribute, and it was eventually proposed by Mr. Dobbing, and seconded by Mr. Hill, that the sum of one guinea be sent from the Association, and this was carried unanimously.

The TREASURER submitted the annual financial statement of the Association, which showed an adverse balance of 11s.

It was pointed out, however, that subscriptions to the amount of £9 19s. 6d. were due from the members, so that the Society was really in a sound condition as to funds.

According to custom the Chair at this stage of the meeting ought to have been taken by the President-elect, but owing to his absence it was proposed by Mr. Snaith, and seconded by Mr. Dobbing, and carried unanimously, that Mr. Dudgeon should continue to occupy the chair until the close of the meeting. The reading of the President's inaugural address was postponed until the next meeting.

Mr. DUDGEON said that he should now like to thank the members for their assistance in making his past year of office a pleasant one. He had done his best to promote the interests of the Association, and thought that the members had also done theirs. He was glad that the matter *re* professional charges had been taken up outside their Association, although not perhaps in quite the way in which he had intended that it should, still it was a matter of some interest that notice had been

taken of the effort of the Association in that direction.

He should like to thank Messrs. Dobbing, Hill, Blackburn and Taylor for the way in which they arranged the details for the picnic of the Association, which was the first the members had had, but he trusted that it would not be the last, for he never enjoyed a day more in his life.

He wished to thank the gentlemen who had kindly read papers, and thought that the discussions thereon had been most interesting and well maintained.

The members then dined together in the hotel.

JAMES H. TAYLOR, Hon. Sec.

The Royal Sanitary Institute—South African Branch.

The South African Branch of the Royal Sanitary Institute are arranging to hold a Congress in Cape Town on November 9th, 10th, and 11th. This is the first sanitary Congress to be held in British South Africa, and it is hoped that a large number of delegates will be sent by the Municipalities and other authorities interested in sanitation. Among the subjects set down for discussion are, the disposal of sewage; the prevention of tuberculosis; the inspection of food; milk supplies; and school hygiene. Papers will also be read dealing with other aspects of public health work.

The South African Branch, which has only recently been established by the Royal Sanitary Institute, seems to be energetically carrying on the traditions of the parent institution, and no doubt its work will have a beneficial effect in the development of public health administration in the Union of South Africa. The Honorary Secretary to the branch is Dr. A. Jasper Anderson, the Medical Officer of Cape Town.

* As Diseased or Exposed to Infection

The Mechanism of Variation in Plants and Animals.

Although "sports" play such an important part in Darwin's theory of the origin of species, he suggested no explanation of their occurrence. It is upon this point that Professor A. Gautier has endeavoured to throw light by a series of researches which have extended over more than thirty years, and the results of which he summarized in a communication to the French Academy of Sciences on September 11th. In 1879 he observed that in plants, at least, variations produced by crossed fecundation cause not only external changes but modifications in the specific molecules of the new being. It has long been known to horticulturists and botanists that the specific characters of the graft may be transmitted to the grafted stock and inversely. All botanists know about the celebrated medlar of Bronvaux, near Metz; it is more than 100 years old, and was grafted upon a hawthorn tree. Every part of the tree above the graft is a veritable medlar, but some years ago, a little below the position of the graft, a branch of medlar grew from the old trunk of the hawthorn, differing from the other branches by bearing thorns; while its flowers, instead of being solitary like those of the medlar, were collected into corymbs like hawthorn flowers. Gautier regards this as showing that the grafted stock was modified in consequence of the conjunction of the two plasmas. This transmission of the characters of one species to another can be more readily shown in herbaceous plants. Professor L. Daniel grafted *Helianthus laetifolius*, a kind of little sunflower, upon *Helianthus annuus*; the former is a perennial plant with a woody stem and well-developed rhizomes swelling into tubers; the latter is an annual plant, the stalk of which is provided with abundant pith, rich in inulin. By the coalescence of these two a race of sunflowers has been produced more persistent than the *annuus* with a hard woody stem having a dark green epidermis bearing numerous lenticles like the stalk of the little sunflower which furnished the graft. M. Jurie, the celebrated producer of hybrids at Lyons, five years ago communicated the case of a vine stock of the variety *Labrusca Isabella*, a dioecious American vine, which was grafted in 1882 with a Poulsard, a hermaphrodite French variety; in 1899 a branch grown from the graft showed the foliage of *Labrusca* instead of that of *Poulsard*, the flowers were as early as those of *Labrusca*, and its fruit intermediate in colour between the two varieties, as Professor Gautier was able to assure himself by personal observation; the tendrils were continuous, generally four or five together as in *Labrusca*; in fact the stock had communicated to a branch of the graft a part of its own specific characters. A similar modification was observed by M. E. Griffon on a branch of almond tree growing on a peach tree which had been grafted on an almond tree, and in many grafts made by Professor Daniel of capsicum on tomato, egg plant on tomato, and so on. These variations are sufficiently stable for them to be transmissible by seed. Professor Daniel has shown that this is so for varieties produced by grafting hedge garlic on cabbage, of Knight's pea on common bean, the plants grown from seed participating in the mixed qualities of the two species. There are, of course, limits to what can be done in this way; it is impossible to make a left-handed screw penetrate a right-handed nut even when thread and diameter are the same, and this is equally true of vegetable plasma. Chicoraceous plants may be grafted on one another, but those varieties which form inulin, a levo-rotatory starchy substance, cannot be grafted on those which form ordinary (dextro-rotatory) starch. The inversion of these two isomers testifies to the inversion of the plasmas which have produced them and explains their non-conjugation.

He compares with this the facts of teleony—that is, where the female which has been impregnated by a male of a different species so as to produce a hybrid, is liable to produce offspring showing similar characteristics, although the latter fecundation is by a male of her own species. A similar law is probably that by which the inoculation of a certain virus modifies the plasma so as to render it for a long time unable to contract the corresponding virulent disease. Prof. Gautier asks what are essentially the modifications which are produced in this manner, and appeals to his observations made during the last thirty years for the answer. It is known that there are some twenty varieties of vine with hermaphrodite flowers indigenous to this continent, and about fifteen varieties with dioecious flowers of the American vine. In the species *Vitis vinifera Europaea*, which comprises all the French vines, there are nearly 2000 varieties, the origin of which is not known, but their external characters suffice to distinguish them. Up to 1878 it was supposed that all the varieties of vegetable species, while differing amongst themselves in shape, in the form of their branches or leaves, in the disposition of their fruit, in its richness in sugar or colouring matter or its forwardness, were yet formed of the same protein, cellulose, colouring matter, and starch; but Professor Gautier, on examining very attentively the pigment of the fruit of the European vine, found that each variety produced in the skin or the pulp of the grape a specific pigment chemically differentiated. He gives the formulae of the pigment in six varieties, showing differences in the amount of carbon and hydrogen. These pigments are all feeble multibasic acids formed by the union of a trivalent radical, and all give by hydrolysis a phloroglucine and an aromatic acid peculiar to each, but always of analogous structure. This holds good for other vegetable families, each variety of acacia producing its special catechin, although these catechins belong to the same family and have the same general structure. In fact, except the ordinary substances, such as sugar, starch, and cellulose perhaps, all the chemical principles peculiar to the species or family, such as tannin, pigment, essences, and alkaloids, vary while preserving the essential features of their common chemical species. Since 1886 Prof. Gautier has explained the sudden variations observed in plants and animals by the coalescence of alien plasmas by which the normal plasma of the creature is modified. The plasma which excites the modification may be brought by insects or microbes, or by moulds acting upon the subterranean parts of a plant. In 1886 Prof. Gautier reported that a branch of moss rose had appeared one day upon a smooth sepal rose in the garden of the Luxembourg. On examining this abnormal branch they found that it bore a certain number of bedeguars having a mossy surface, which were produced by the puncture of a *Cynips*, which communicates to the rose tree and to the gall in which it deposits its larva the property of producing the mossy excrescences which characterise it. In 1889 MM. Charabot and Ebray showed that the puncture of an insect may cause certain stocks of peppermint to produce branches whose inflorescence resembles that of a neighbouring genus, the basilic (*Ocimum basilicum*), while according to Meehan, when the roots of *Liatria* and *Vernonia* are attacked by the mycelium of a mould their flowers become completely altered, their anthers remain sterile, and from being hermaphrodite these flowers become unisexual, as if some virus like that of the vaccine virus modified the plasma of the plant and its function. Moreover, if we deprive a plant of one of its natural zymases necessary to its normal development, it may undergo such changes as to resemble a new species; thus, in cutting the stalk of maize down to the ground at the moment when the male pannicle is about to develop, the maize known as Pennsylvania maize changes into *Zea mais pseudo-androgyna*, a new

species capable of being transmitted by seed. No doubt these great and sudden modifications of race and species are not always transmissible by seed, but they fail altogether to conform to the rules of slow and successive adaptation, and they only occur in a small number of individuals amongst thousands submitted to the same external conditions. The modifications which supervene in this way involve a transmission of the fundamental constituents of the new being; but, far from being monstrous, the variations in the individuals and races so produced do not, as a rule, transgress the limits beyond which the anatomical resemblance would disappear, while the specific principles of which their plasmas are constructed preserve their general chemical structure while undergoing modification.—*B.M.J.*

Cruelty Case at Hull.

At the East Riding (Hull) Police Court, on Wednesday, 11th inst., John Wilcox, a labourer, of 4 Rosebery Terrace, Newland, was summoned at the instance of the Hull and East Riding S.P.C.A., for working a brown horse in an unfit condition at Cottingham, on September 20th. Herbert Atkinson, dairyman, of Hull Road, Cottingham, was summoned for causing the horse to be worked.

Mr. G. S. Williamson prosecuted, and Mr. J. H. Payne defended.

Sergeant Sweeney gave evidence that he saw Wilcox driving the horse along the Hull Road, on September 20. The animal was lame and apparently in great pain. It was unfit for work, and on his advice Wilcox took the animal in.

Inspector Chivers stated that he examined the animal in the afternoon of the day in question in the defendant's field. It was extremely lame on the near fore leg, due to atrophy of the frog. The animal was in great pain. He saw Mr. Goodall remove several large live maggots, which were eating into the frog. It was in an incurable condition. It was lame to-day and not fit for work.

Mr. Goodall, M.R.C.V.S., of Hessle, said the horse's condition was due to absolute neglect. He took out a quantity of dirt and a nest of maggots from the cleft of the frog. He examined the other leg. There was supuration from the other foot, and more maggots in the hoof.

Mr. W. P. Ruthven, M.R.C.V.S., of Beverley, said he examined the horse on October 5th, and found it in great pain, and after he had examined the foot he had come to the conclusion that the horse had been lame for a long time. The animal could not have been fit to work on September 20th, as it was not fit for work when he examined it on October 5th.

Atkinson said that the horse was between 25 and 30 years old. For the past six years it had done no regular work and the reason he kept it was that his father was fond of it. He did not know on the day in question that the animal was in the condition described by the prosecution.

Mr. Frank Bradley, M.R.C.V.S., of Hull, said he examined the horse at the defendant's premises on Sept. 20th. It was in good condition generally. It was mechanically lame, without disease, and not in any pain at all. He examined the foot carefully, and found no sign of disease. There were no maggots. There was a slight moisture, but only such as was caused in all horses' feet when turned out to grass.

Ernest Thomlinson, blacksmith, said he shod the horse on September 23rd. There was nothing serious the matter with the feet. They wanted dressing a little, but it was impossible that they should be rotten on the 20th.

Mr. Harry Sowerby, M.R.C.V.S., said he examined the horse on October 2nd, and found no trace of disease in

the horse's foot at all. It was an old horse and in good condition. It was quite fit for work on that day. The animal was suffering from rheumatism.

The magistrates, after lengthy consideration, came to the conclusion that they would convict, though the circumstances did not justify a severe penalty. Atkinson was fined 10s. and costs, and against Wilcox judgment was respited.—*Hull News.*

Veterinary Degrees in the University of Edinburgh.

A scheme of co-ordination has been arranged between the University of Edinburgh and the Royal (Dick) Veterinary College, whereby the degrees of B.Sc. and D.Sc. in veterinary medicine will be awarded. The scheme, which awaits the approval of the Privy Council, provides for one year of study to be spent at the University and four academic years at the Veterinary College.—*Lancet.*

Renewal of Mr. Trigger's Mayoralty.

The Newcastle Town Council having extended to the present Mayor (Mr. R. C. Trigger) a unanimous and enthusiastic invitation to fill the office for a second year, we are pleased to report that his Worship has accepted the invitation. Mr. Trigger has fulfilled the duties of the Mayoral office with dignity and with a devotion that has meant much personal sacrifice. The responsibilities of the office have also been discharged with judgment and courage, and the extreme popularity of Mr. Trigger's Mayoralty is evidenced by the unanimity of the Council, and even more strikingly by a petition presented to his Worship prior to the announcement of his decision. The deputation who presented the petition was introduced by the High Constable (Mr. A. G. Leighton), and consisted of the rector (the Rev. J. W. Dunne), the Rev. J. Clavin (Roman Catholic), Dr. R. H. Dickson, Mr. A. Mandley, J.P., and Mr. H. White. The petition they presented expressed entire approval of Mr. Trigger's fulfilment of the office of Mayor, and urged his acceptance of the office again. The signatories, who numbered 62, were representative in a remarkable degree of the most influential inhabitants of the town, including representatives of all religious denominations, the professions, and the trade of the borough. In the face of that request his Worship felt that a refusal of the invitation was hardly possible. It is specially opportune and appropriate that the annual show of the Staffordshire Agricultural Society will be held at Newcastle during Mr. Trigger's second year of Mayoralty.—*Staffordshire Advertiser.*

ARMY VETERINARY SERVICE.

Extract from *London Gazette*,

WAR OFFICE, WHITEHALL, Oct. 13.

REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. W. S. Anthony to be Maj. Dated Oct. 14.

Eight oxen and a dozen pigs were roasted whole on spits in front of fireplaces erected in the streets of Stratford-on-Avon last week, at the annual mop-fair, which dates back to very early times—probably to Richard I., who gave Stratford its first market charter.

Mr. JOSEPH P. RAILTON, M.R.C.V.S., is this year Vice-President of the Builth Wells Horse-Shoeing Society, and was donor of the First Prize at the recent competition.

OBITUARY.

GRAY.—On the 15th inst., Alfred Gray, The Wantz, Dagenham, Essex, youngest son of the late Henry Gray, The Lodge, Barking, and father of Henry Gray, M.R.C.V.S., in his 83rd year.

Memorial to Mr. G. Stewart.

The burial place of a worthy citizen of Rothiemay, Mr. George Stewart, v.s., has hitherto remained unmarked by any memorial stone, but this omission has now been made good by the kind liberality of Mr. Lipp, Haddoch. Mr. Stewart in his day was a noted veterinary surgeon, and his practice extended over a wide district, including all the neighbouring parishes. He was trained to his profession in the Dick Veterinary College under Professor Dick himself, and he often spoke of his famous teacher. Perhaps his claim to be remembered rests chiefly on the advice he gave when cattle plague was introduced into our country from Russia in 1865. The dreaded disease had been brought into Huntly by four calves from the south. The question how to deal with it was being discussed by the Huntly farmers when Mr. Stewart advised that it should be stamped out with the pole-axe. The Aberdeen authorities, and later the Government, adopted this advice, and thereafter the disease was gradually overcome.

In addition to his veterinary work Mr. Stewart was something of a doctor, and dislocations, broken bones, and other ailments were brought to him for treatment. Over and above all, he had studied human nature, and the penetrating eye, set in a strong countenance, made him as successful in dealing with men as his veterinary knowledge did in curing animals.

The memorial erected by Mr. Lipp bears the following inscription:—"In memory of George Stewart, v.s., who died at Milltown of Rothiemay on the 21st August, 1874, aged 56 years. One of the ablest veterinary surgeons of his day, he averted a great disaster to the agricultural community by his prompt action in connection with the outbreak of rinderpest in the year 1865. Erected in remembrance of his valued services."—*Aberdeen Free Press*.

The Late Mr. Lees.

Mr. Robert Lees, M.R.C.V.S., Lagg, Ayr (notice of whose death appeared in our issue of last week), was one of the most outstanding personalities among the farmers of the western shire. "Lagg" was a splendid example of the resolute Scot who does not understand the meaning of the word "beaten." He was born in Tarbolton parish, and practised for a time as a veterinary surgeon, but that occupation was a bit slow and one-sided for him, and he embarked on farming on "the shore." To say that he excelled as a farmer would be to speak the language of irresponsible courtesy. His was too eager a spirit to take account of the many details which go to make up successful farming, and Mr. Lees was too fond of action and excitement to settle down to that sort of existence. He became an enthusiastic breeder of Blackface tups, and gave himself to the task with all the energy of a singularly eager nature. He acquired high distinction in the business, and bred some notable rams by which modern Blackface history has been moulded. Mr. Lees was a warm-hearted Scot, with the traditional ambition of the best of his race to give his family a first-rate education, and so let them start in the world with at least the indispensable capital of character and intelligence. How well his children—both boys and girls—responded to their father's ambitions is known to all who are acquainted with the family. Alike in Ayr Academy and at the University the Lagg boys gave a splendid account of themselves,

and in their own departments the girls were not behind. All are acquainting themselves well in the learned professions which they adorn, and cherish a deep regard for the rough and ready eager Scot who did everything a parent could do to give them a good start in the race. That our deceased friend was pardonably proud of his family we all know, and none grudged him this best reward of a parent's toils. We shall miss "Lagg." He did not know how to take things easy. It was obvious to many that he had recently lost somewhat of his old buoyancy of spirit, and at Lanark ram sale a month ago he turned seriously ill, and had to go home. He rallied a little, and was out and about—few who met him during these last weeks realising how much he suffered.—*The Scottish Farmer*.

COLLEGE CREST APPEAL CASE.

Sir,

Being in doubt as to whether the bulk of the profession are acquainted with the facts of this case I appeal to you through the medium of your valuable journal to give the matter that amount of publicity which the case assuredly deserves.

I daresay quite two-thirds of the profession have been using the crest on their professional notepaper for a great number of years, and rightly so. The late Inland Revenue recognised that right. Since their disappearance the various County Councils, ever ready to increase their revenue, have zealously interested themselves in this matter in order to penalise every member who uses the crest.

The question is, Have we a right to use the crest without a licence? I maintain that we have that right, not only because the annual fee of a guinea is regularly paid by the Royal College of Veterinary Surgeons, but because the crest appears on the face of our diplomas, has been sanctioned so long, and is in no wise to be considered analogous with the use of a family crest and coat of arms. To my way of thinking the County Council have no right to interfere and tax our members who have used the crest by custom. It must be patent to all that it must be of inestimable value to the numerous County Councils to be allowed not only to charge the Royal College of Veterinary Surgeons the usual fee but also to inflict payment upon each member who persists in using it. I believe a number of practitioners have paid a small penalty and discontinued the user rather than face legal proceedings. On principle I refused to do this, and was accordingly proceeded against by summons. The case was heard at Bow Street Police Court and dismissed by the learned Magistrate, Mr. Curtis Bennett, who allowed me three guineas costs. An appeal was afterwards lodged, and a case has been stated by the Magistrate.

I am willing to fight the case right through, and the matter will be settled once and for all, but in fairness to me I really think the profession should rise to the occasion and assist me pecuniarily to meet all costs should the magistrate's decision be reversed. Prof. Woodruff has been particularly interested in the matter, and it is owing to his unflagging energy and kindness that a sum of £27 has been collected. Little time is to be lost now, for I hear that the appeal stands 30th on the list.

I venture to hope that there will be a more generous response to the fund during the next week. £27 is obviously inadequate to meet all costs, which at least cannot be far short of £100. Any members desirous of assisting me will naturally be assisting every member of the profession in resisting the local taxing authorities.

All donations may be sent to Prof. Woodruff, of the Royal Veterinary College, Camden Town.—Yours faithfully,

Wm. Kirk.

BRONCHITIS

ASTHMA
BROKEN WIND

A combination of the sedative properties of heroin and the stimulating action of terpin hydrate is particularly well adapted to the requirements of the veterinary profession.

ELIXIR HEROIN & TERPIN HYDRATE (P., D. & Co.)

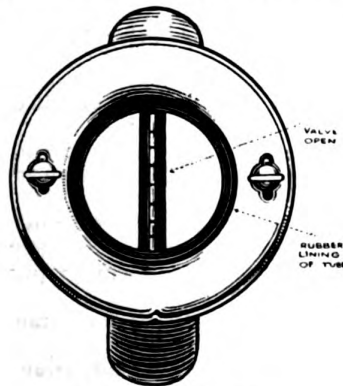

is highly commended by prominent veterinarians. It simultaneously soothes and gives tone to the affected mucosa of the throat, liquefies bronchial exudations and promotes their expulsion. It reduces temperature and improves respiration. It is particularly valuable in the treatment of equine pneumonia, and in asthma or other bronchial troubles of pet dogs.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Price with 2 Steel Needles in Metal Case—20c.c. 21/- 10c.c. 17/6. 5c.c. 15/- 2c.c. 10/- 1c.c. 9/-

GLANDERS

A Clinical Treatise, by William Hunting, F.R.C.V.S.

Chief Veterinary Inspector to the London County Council.

SOME PRESS NOTICES:

THE HOSPITAL.

"The treatise is complete without diffuseness, scientific without being unpractical, and throughout eminently lucid. Of the appendix on glanders in man we will only say that we could wish it reproduced in text books of medicine just as it stands. The book is excellently produced, and illustrated with a series of coloured plates by Mr. S. A. Sewell which are well worthy of the letterpress."

THE BRITISH MEDICAL JOURNAL.

"The book is the outcome of unique opportunities and from the clinical and hygienic point of view it is extremely valuable. . . . One of the most valuable features of the book is a series of fourteen beautifully executed coloured plates showing typical lesions of glanders in horses."

THE VETERINARY JOURNAL.

"To praise it too highly would be impossible, for nothing equal to it has ever appeared before, and even our continental colleagues must yield on this occasion. . . . The coloured plates and photographs are simply superb."

THE FIELD.

"This book should be found in every public library, and no medical student should fail to assimilate its contents. It will doubtless find a place in the library of country gentlemen and all who take a deep interest in the horse."

THE VETERINARY NEWS.

"For the work itself we have nothing but the highest praise. The printing is excellent, the plates could not be excelled, and the binding is on a standard with the rest of the work."

THE SCOTTISH FARMER.

"This is a splendidly got up volume and evokes admiration. We trust the enterprise of author and publishers in issuing such a work will be richly rewarded."

THE JOURNAL OF COMPARATIVE PATHOLOGY.

"For many years past Mr. Hunting has been generally recognised as the chief authority in this country on glanders regarded from a clinical point of view, and in this monograph he has given the profession the benefit of his long and intimate study of the disease. . . . The book will prove well-nigh indispensable both to veterinary students and practitioners."

COUNTY GENTLEMAN.

"The best book on glanders."

THE SCOTSMAN.

"The volume is an evidence of the high competence which veterinary science has reached."

LIVE STOCK JOURNAL.

"The volume deals with glanders in all its phases, and also with the dangers of infecting human subjects with this disease."

THE NORTH BRITISH AGRICULTURIST.

"This is a massive and handsomely got up work by a man who thoroughly understands his subject."

THE FARMER'S GAZETTE.

"In the appendix is an interesting account of glanders in man A prominent feature of the book is the beautifully reproduced water-colour drawings. The colouring of these is very true to nature."

THE MORNING POST.

"Mr. Hunting is Chief Veterinary Inspector to the London County Council. The post-mortem examinations made for that body have furnished him with a unique collection of glanders lesions."

THE SPORTSMAN.

"For this valuable work Mr. Hunting deserves the thanks of all horse-breeders and owners. . . . Much has to be done before we finally get rid of glanders, and to this desirable consummation Mr. Hunting has contributed splendid assistance by the book under notice."

THE ROYAL DICK COLLEGE MAGAZINE.

"The veterinary profession, not only in the United Kingdom but throughout the world, is greatly indebted to Mr. Hunting for putting the results of his experience on record and within the reach of all. . . . The illustrations alone are an invaluable addition to the library of any practitioner, and their educational value to the student will be fully appreciated."

THE VETERINARY RECORD.

"If the text is a mine of clinical wealth, the photographic and coloured plates are examples of the highest artistic talent. Nothing like them has ever previously been attempted in connection with glanders. To the present generation they indicate in the most natural manner what many men never have seen, while to posterity they will remain a record of a loathsome disease which in time will be as dead in these islands as pleuro-pneumonia or rabies."

The publisher is to be congratulated on his share of the work—good paper, fine print and admirable binding combine to make a handsome volume."

THE JOURNAL OF ECONOMIC BIOLOGY.

"There is little doubt but that so valuable a contribution to the literature of veterinary pathology will find a place in the library of everyone who has to deal with diseases of the horse. It is ably written, and leaves nothing to be desired in the manner in which it has been presented to the public."

THE ESTATE MAGAZINE.

"Probably the most authoritative and comprehensive work on glanders that has yet seen the light."

THE LANCET.

"The work under review will be the standard work of reference on this dreadful scourge of the equine world for many a year if we mistake not. . . . The subject is treated from every point of view which is likely to be of value, and this small book is equally of interest to members of the medical and veterinary professions. No medical officer of health and no hospital library should be without it."

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1216.

OCTOBER 28, 1911

Vol. XXIV.

BOVINE DISEASES.

Of late we have had quite an unusual number of articles and communications upon a class of subjects which have been neglected by British veterinary writers, viz., bovine diseases. Two good results have followed.

In the first place, we have learned something of a bovine skin disease which does not seem to have been hitherto described, but nevertheless appears to have been somewhat common recently in various parts of the United Kingdom—for there is little doubt that the descriptions given by Messrs. Hoare, Hills, Golding, and Airey relate to one and the same affection. It is a benign but by no means an unimportant affection, the pathology of which is still obscure; and its recent recognition by clinicians is a distinct addition to our professional knowledge.

In the second place, we have had several comprehensive articles by different practitioners upon the much wider and more important question of bovine digestive disorders. These also, in the gross, will well repay perusal and re-perusal. They mark no great advance, but they stimulate independent thinking; and they illustrate a truth which some members scarcely yet fully appreciate. They show how wide and complex a field of study bovine digestive disorders present, and how little is certainly known regarding many of its problems. Very little of note has been written upon the question by our countrymen, and the result—especially when we consider the every-day importance of the subject to the country practitioner—is not creditable to us as a profession. Broadly it may be said that the sporadic diseases of the bovine omasum, abomasum, and intestines, as regards their pathology, diagnosis, and therapeutics alike, are still practically unexplored ground. Probably their clinical differentiation, like that of the equine colics, will always form very debateable ground; but it is quite certain that we might learn more of the diseases themselves than has been learned yet.

We shall only do so in one way—by careful clinical observation, checked whenever possible by post-mortem examination. The recent articles made it clear that some practitioners are working at the question on these lines as opportunity offers, and their work should stimulate others to follow their example. In so wide and obscure a subject, advance is most likely to come from a comparison of the experience of many men, and country practitioners might well take up the study of bovine digestive disorders. The whole subject is a more important branch of country veterinary practice than it ever has been before; it is still one of the least understood, and it is one of the few that can only become better understood by the observations of country practitioners.

CONGENITAL DIAPHRAGMATIC HERNIA.

By W. R. DAVIS, M.R.C.V.S., Enfield.

In May last I was sent for to attend a valuable thoroughbred foal, three weeks old, which had been previously quite healthy but on this morning, after being turned out with its dam in a paddock, was found standing by itself and breathing quickly and with difficulty.

With its dam it was immediately put in a box. I found the temperature to be 103, and the pulse not greatly disturbed. The nostrils were somewhat dilated, and the breathing, though faster than normal, was not very rapid, it was, however, what might be characterised as disordered. The ribs showed up very prominently, and the abdominal walls rose and fell in an irregular manner, in fact one would have said, a broken-winded foal. On auscultating the chest I could hear no respiratory murmurs whatever on the left side, but in their place sounds that were distinctly intestinal. On the right side loud vesicular murmurs could be heard, but here, too, intestinal rumblings at times quite obscured them. The foal had emptied the mare's bag and seemed quite cheerful.

I told the stud manager that the case was peculiar, and that, though it could hardly be the case, it seemed to me that the bowels were in the chest among the lungs. I advised him to report the case as congestion of the lungs, and to state that the foal was in a serious condition.

The mare and foal were kept in the box for three weeks, the little patient emptying the bag and keeping quite lively; temperature and heart beat being about normal, but the respirations continuing much the same. There was no cough, and no discharge from the nose. When I coughed the foal I got a distinctly broken-winded cough from him.

One day the mare was given tares, of which the foal also partook, this gave rise to indigestion and diarrhoea, followed by a pronounced attack of dyspnoea.

All this time on auscultating the chest the intestinal rumblings could be heard, particularly on the left side, and respiratory sounds only on the right side. I now had the mare and foal turned out to grass for a few hours in the early morning. The foal galloped about, but quickly came to a standstill, legs apart, nostrils dilated, flanks heaving. After a while he recovered and gravely followed his mother.

At this time I came to the conclusion that a portion of the lung had remained in a state of foetal collapse and that there was emphysema of the rest of the lung, and advised that the foal should be

put away as never likely to make a racehorse. The owner wrote to say that if that was my opinion we had better destroy the foal.

A few days after these instructions were received, and while we hesitated about carrying them out, our patient had a violent attack of colic and died.

Post-mortem. On removing the ribs a mass of the small intestines, dark-red and filled with bloody fluid, was found in the chest cavity, where also a portion of the colon and most of the cæcum together with the left lobe of the liver were lying. They had gained access to this cavity through a large orifice in the diaphragm, low down and towards the left side, the hiatus being due to a want of soldering between the phrenic and muscular parts of this curtain.

The anterior part of the lung was collapsed, the posterior part emphysematous, while the right lung, though anæmic, seemed fairly normal. Death was due to strangulation of the intestines.

VETERINARY REPORT ON THE FRENCH OPERATIONS IN MOROCCO FOR THE RELIEF OF FEZ, 1911.

La Semaine Vétérinaire for the 15th July, publishes the following interesting account of the working of the Veterinary Services in Morocco, by M. le Vétérinaire en premier Fraimbault.

"There was no proper organisation as in the former Colonial Expeditions to Madagascar and China, a Director of the Veterinary Service not having been appointed. The equipment of the Columns with veterinary medicines and stores, which were very limited, was entrusted to 1st Class Veterinary Surgeon Belleval, the S.V.O. in the Shawia district, and Director of the Casablanca garrison infirmary. He had also to post to the different columns the Veterinary Officers, according to their length of service in the colony or the date of their landing in Morocco.

"All the Veterinary Officers arriving from France in charge of animals were provided with the regulation canteen, also the following units, Battery, Squadron, Senegal battalion and the Mounted company of the Colonial Infantry, were similarly equipped.

"Those Veterinary Officers who came out unattached to units had, on their departure to the front, to provide themselves with veterinary chests, which were generally cut down, and some indispensable instruments omitted, on account of difficulties which were experienced in obtaining transport. Some units and small detachments which had requisitioned veterinary stores were provided by M. Belleval on their departure from Casablanca, with certain compounded drugs for the treatment of those diseases which occur most frequently in the field.

"Owing to the large number of injuries of every kind, of which the most severe were caused by pack saddles, the supply of veterinary stores was soon exhausted, and hardly any remained when Fez was reached. Later, on the organization of the Supply Services, 1st Class Veterinary Surgeon Guenot was

able to send forward certain veterinary stores from Mehedia, the supply base, and it was also possible to purchase certain stores at Fez at a reasonable price.

"While the Medical Service has appeared to me to be perfectly organised throughout this Campaign, the Veterinary Service has, in comparison, been deficient in personnel from the beginning, and the supply of medicines and dressings has been very insufficient. Until the columns set out to the relief of Fez, they had but two 2nd Class Veterinary Officers, with only a Veterinary Cantine for the most important units. Each of the Veterinary Officers, accompanying a column have had a platform cart, mule, or camel placed at his disposal for the transport of the necessary equipment.

"Three Veterinary Officers accompanied the Columns on the march to Fez; 2nd Class Veterinary Surgeon Charvot with Brulard's Column, with which he remained throughout the whole Campaign; 1st Class Veterinary Surgeon Fraimbault and 2nd Class Veterinary Surgeon Millet with Dalbiez's Column.

"Some days later, Assistant Veterinary Surgeons Pflieger and Carpentier arrived at Fez with Gouraud's Column. The Veterinary Service was now organised as follows:

"There were three Senior Veterinary Officers. At Casablanca, the S.V.O. of the Army, M. Belleval. At Mehedia, the S.V.O. of Transport, 1st Class V.S. Guenot, who managed a depot of injured animals and supplied the Veterinary Officers at the front with stores. At Fez, the S.V.O. at the front, 1st Class V.S. Fraimbault, with Assistant V.S. Pflieger attached, in charge of an important depot of injured animals.

"The three Columns, Dalbiez's, Brulard's and Gouraud's based on Fez, had each one or two Veterinary Officers, Rousselot, Colette, Carpentier, and Chalvat. In addition, two or three other Veterinary officers (Germa and Monnier) were distributed along the Line of Communication, making altogether a total of twelve, of whom four were 1st Class Veterinary Surgeons, the number of Veterinary Officers attached to the disembarking units.

"The columns were made up of all branches of the Service, with an important convoy of pack mules from Algeria and Camelo. They returned periodically to Fez with a large number of casualties amongst the animals. The injuries, almost all caused by pack saddles, were usually very severe, the result of badly balanced loads, and overloaded animals remaining too long under the saddle. After operations lasting only 30 days, it was not unusual to see enormous fistulous withers and large sloughing areas of skin exposing three or four ribs, but these wounds, which were in every case covered with dust, healed quickly in spite of their severity.

The depot of sick animals at Fez.—This depot was attached to the transport and possessed no equipment. The sick, to the number of nearly 200, were placed on picket lines under the supervision of a quarter-master, in the midst of a camp situated about 1½ miles from Fez. They were exposed to the full glare of the sun, and tormented by flies,

which did not give them a moment's peace, and caused them to rub and roll in order to obtain relief. The majority were suffering from pack saddle galls, necessitating surgical interference, others from gunshot wounds. The remaining animals under treatment were chiefly large Artillery horses, exhausted by fatigue, which were almost impossible to resuscitate, owing to the lack of forage, hay or straw.

"The professional work began each morning at 6 o'clock and was never finished before 10 or 11, this, owing to the great heat, was very trying.

"The animals of the Columns, which were given a ration of inferior barley on the march, were turned into fields of standing barley or wheat at the halting places on account of the difficulty of transporting the forage.

"During the rapid march of the columns on Fez, all the animals displayed considerable powers of endurance. The relieving troops accomplished 10 marches of about 25 miles each, without a day's halt between Casablanca and Fez. It is true that it was at a favourable season, the heat being quite bearable, the nights cool, and the country flat except in the neighbourhood of Fez; all the rivers were fordable except the one at Rabat, and not a drop of rain fell. Nevertheless, since it was necessary to march quickly and to arrive at all costs, some losses from overwork resulted, and a certain number of exhausted mules, which were unable to keep up, had to be destroyed.

"In this rapid march upon Fez, the camels had no opportunity of grazing, and as they were given no grain rations, wastage quickly began, and there were considerable losses amongst them.

"Blood examinations, made by Hormus, showed no evidence of Trypanosomes or Piroplasms, which might have been expected from the numerous dull flies (taons) attached to the thighs, and from the progress of the cases, which at first exhibited a high temperature, followed by emaciation, want of appetite, and, towards the end, diarrhoea.

"Up to the present time no contagious disease has been recognised in the columns, nevertheless rigid sanitary measures have been ordered to safeguard our units from glanders, which exists amongst all the tabors of the Moroccan Cavalry. This affection, which has been thoroughly studied since our arrival at Fez, had never been seen in the district of Shawia—Has it been introduced by some one? It has been demonstrated by post-mortem examinations, mallein injections, and the inoculations of a donkey foal, that it is really glanders, and not an affection simulating it which is only slightly contagious, and would consequently be only relatively dangerous to our animals.

"The tabors of the Moroccan Cavalry are seriously infected, and it has been necessary to destroy a certain number of horses.

Sanitary inspections, extending over some days, have enabled us to isolate the doubtful cases, but it is only by malleining all the animals that it will be possible to eradicate this formidable disease, which is a serious danger to our units, and prevents the Moroccan Cavalry being more actively employed with our columns.

"The Army of Morocco consists of a certain number of tabors of Cavalry, Infantry, and Artillery, with a detachment of Engineers; the tabor of Cavalry corresponds to a squadron, and that of Infantry to a battalion. The total strength of horses and mules at Fez is over 1200. When we arrived at Fez all the tabors were encamped near the town; since then some have been moved to certain important centres.

The Moroccan Army, which is commanded by French Officers and non-commissioned officers, is to be reorganised and increased. Provision has been made for three Veterinary officers, of whom one is to be a Veterinary Officer of the 1st Class. This number will not be sufficient, on account of the disease which has spread throughout the Cavalry." — (*Revue Générale de Médecine Vétérinaire*, 15th Sept., 1911).

Military readers will find interesting notes of the operations which were carried out during the period covered by the above report in the Journals of the Royal United Service Institute for May, June, July, and August, 1911.

L. J. BLENKINSOP, Colonel A.V. Service.

REPORT OF THE ARMY VETERINARY DEPARTMENT WITH THE SUAKIN FIELD FORCE, FROM THE 14TH MARCH TO THE 14TH MAY 1885.

From the Principal Veterinary Surgeon in Egypt to the Principal Veterinary Surgeon, War Office, London.

Head-Quarters, Cairo, 25th June, 1885.

Sir,—I have the honour to forward the following report on the working of the Army Veterinary Department with the Suakin Field Force, during the recent military operations in the Eastern Soudan, from the 14th March to the 14th May, 1885. These dates may be considered as representing the commencement and termination of the campaign.

You are aware that, owing to the great strain on the Department, caused by the requirements in India, Egypt, and the Cape, the number of Army veterinary surgeons employed with the expedition was out of all proportion to the complement laid down in the Veterinary Regulations; and that, at no period of the campaign had I more than nine executive officers for duty with upwards of 13,000 animals. I do not include the veterinary surgeon of the Australian Contingent, whose duties were entirely confined to the horses of the New South Wales Artillery.

The promptness with which you responded to the application for more officers, which I caused to be telegraphed from Cairo on the 27th February, 1885, did much to relieve the strain; but had the campaign been prolonged, it would have been necessary to have considerably augmented the department.

When it is taken into consideration that each executive veterinary surgeon was more or less responsible for the health and efficiency of many hundreds, and, in some cases, thousands of animals; that his charges were frequently scattered over miles of ground; that the nature of his duties required him to be in the saddle for many hours daily, exposed to the tropical heat of an unhealthy climate; that in many cases he had to work with an insufficient staff, and often under great disadvantages, the unduly heavy and harassing nature of his duties will be understood, and the reason afforded why the health of so many of our officers broke down.

Notwithstanding these facts, the veterinary duties were zealously and efficiently performed; and it is satisfactory to remark that not a single complaint from any of the various officers commanding mounted troops or transport corps, was received by me at any time during the campaign.

On assuming the administrative veterinary charge of the field force, and having made myself familiar with the organization of, as well as the distribution of the animals belonging or attached to, the various regiments or corps, I proceeded to make as fair a division as possible of the executive duties, taking into consideration the special qualifications of each individual officer.

A veterinary surgeon was appointed as sanitary officer on Quarantine Island, for the purpose of inspecting all ships arriving with Government animals, and examining all animals immediately on landing, with the view of preventing the introduction of contagious diseases. The duty was efficiently performed, in the first place, by Veterinary Surgeon Sharp, and subsequently by Veterinary Surgeon (First Class) Gillard.

In order to facilitate the treatment of the more serious cases of sickness and lameness amongst the horses, and for the purpose of keeping the mounted troops at the front as effective as possible, I caused a veterinary hospital to be established at the base, under Veterinary Surgeon Aitkin, assisted by a Farrier Quarter-Master-Serjeant and two shoeing-smiths. Temporary stabling for 80 horses was erected, and adequate arrangements were made for shoeing. I consider the work done at the Base Hospital to have been highly satisfactory. Not only were the stables nearly always full, but numbers of animals under treatment had to be picketed in the lines.

In consequence of the skill, care, and attention paid to the cases by Veterinary Surgeon Aitkin and his assistants, many valuable animals were saved, which, under less favourable circumstances, would probably have been lost to the service.

Owing to the arduous nature of the veterinary duties, it was impossible to expect the case books to be kept up and returns furnished, as on home service. I, therefore, directed that the cases should be entered in the Register only, and none but important ones recorded; also, that half-monthly returns should be rendered, with the diseases grouped. This system, I found, relieved the veterinary officers of much unnecessary labour, and worked very satisfactorily. Each officer was, of course, responsible for the correctness of his statistical information.

With the view of detecting and suppressing contagious diseases, careful sanitary inspections of all animals, lines, etc., were periodically and systematically made, and directions given for isolating, and placing under close observation, cases of a suspicious nature.

On account of the presence of contagious skin disease amongst the transport camels landed for the use of the expedition, and the necessity for segregating the animals affected, a lazaretto zereba was formed on the 18th March on a convenient site, affording sufficient protection from the enemy, for the reception of contagious cases. An adequate staff was appointed under the supervision of Veterinary Surgeon (First Class) Rayment, and Farrier Quarter-Master-Serjeant Smith, of the Commissariat and Transport Corps, was placed in immediate charge. The services of this non-commissioned officer are well worthy of special consideration, for his duties were extremely arduous, and carried out in a highly praiseworthy manner.

The result of the establishment of this zereba has been most satisfactory. Upwards of seven hundred cases were admitted to treatment up to the 14th April, when, owing to the precautions taken, parasitic skin disease became practically stamped out. On this date

arrangements were made for changing the ground, and converting the zereba into a general sick camel infirmary, which worked well up to the termination of the campaign.

A veterinary store was established under the supervision of Veterinary Surgeon (First Class) Gillard, at the base, immediately on receipt of the medicines and surgical appliances from England. A properly organised system of accounts was adopted, and arrangements were made for the speedy transmission of medicines on requisitions to veterinary surgeons at the front. The duties connected with this establishment were very efficiently carried out by the veterinary officer in charge.

In addition to the veterinary stores from England a number of small chests termed "unit cases," were forwarded by my direction from the veterinary stores at Cairo, for use during the campaign. Each of these cases contained an assortment of camel medicines for internal and external use, and they were sufficiently portable for either camel or mule transport.

The veterinary field wallets sent out for use with the expedition are, in my opinion, very complete, and deserve to be ranked amongst the most valuable of the veterinary appliances provided for active service. The military operations were, however, not of sufficiently long duration to give them an extended trial; but those which were issued by my direction to the farriers of mounted corps were of great use on several occasions, when the larger field chests were not available. For flying columns and small detached mounted parties, they are invaluable.

A Remount Depot was established at the base, under the command of Major Anstruther, D.A.A.G., and subsequently under Major Lloyd, 20th Hussars, assisted by Veterinary Surgeon Aitkin. The arrangements were very complete, and the working of this establishment was satisfactorily carried out.

The only actual remounts received was a batch of 145 horses and ponies which arrived from India on the 30th March for the Guards' Mounted Infantry. The remainder of the animals at this depot were principally transfers from regiments and corps.

The shoeing was conducted by the base hospital farriers, and the official books were supplied from the stock forwarded by you for my use.

An advanced Veterinary Hospital was formed at Handoub, about ten miles from Suakin, on the 18th April, under the supervision of Veterinary Surgeon (First Class) Gladstone, assisted by Veterinary Surgeon Betser, who also had charge of the Lines of Communication to Tambuk. An adequate supply of medicines, etc., was forwarded from Suakin, and all the necessary arrangements made for the reception and treatment of animals at the station, and if necessary from the advanced posts of Otao and Tambuk.

The duties of this establishment were carried out very efficiently.

The horses and mules were kept fairly well shod up during the campaign, and the shoeing was on the whole, good. The system of "cold fitting" was, on my recommendation, generally adopted, and the new pattern machine-made shoes and nails were used, as far as was practicable, especially amongst the lighter horses. I believe this is the first trial on active service. Their principal advantages appear to be:—

1. The ease and celerity with which they can be fitted cold.
2. The superior quality of the iron.
3. Their lightness, durability and finish.
4. The fact that the heavy field forge, with the fuel and plant for shoe-making, can be dispensed with; the small pack forge being merely necessary in the few cases where heat is required.

The immense advantages of the latter, especially in a campaign in the desert, where wheel transport is almost impossible, can be readily understood.

The staff of farriers and shoeing-smiths with the field force was sufficient for all requirements, but, with the exception of the eight shoeing-smiths who arrived from England under Farrier Quarter-Master-Serjeant Kemp, 20th Hussars, on 17th March, and whose services were at once utilised, there was practically no reserve to fall back upon in the event of sickness or other casualties occurring. Had the military operations been prolonged, the absence of a sufficient reserve of farriers might have been a matter of serious moment.

The sanitary arrangements of the camps and zerebas, from a veterinary point of view, were as good as were possible under the circumstances. Constant personal attention was paid both by myself and the veterinary officers under my supervision, to this important feature, and any suggestions made were promptly carried out.

The forage issued for the use of the troops was fairly good in quality, and sufficient in quantity. English hay and oats or compressed forage, were principally supplied for the use of the English horses, except during the latter part of the campaign, when a proportion of Indian hay was substituted. In many cases the compressed forage was found to be musty, and some of the bales I examined were mouldy. This, however, was the exception.

The horses of the British Cavalry Brigade were fed for some six weeks upon Graves' grain cake, together with either the hay cake or baled hay. All of this grain cake that I examined was in good condition, and I consider it to be an excellent form of portable forage for service. Both this and the hay cake should be used with the improved nosebag. The native horses and mules were fed on barley and chopped straw.

The Indian contingent made their own forage arrangements; the grain, hay, and other classes of food were apparently of good quality.

The tiben, beans, and barley supplied for the use of the camels were excellent. I experienced some little difficulty at first in getting the barley crushed. The beans were all split. Bran was supplied as required.

It was impossible to procure green food for the sick horses and mules, but a sufficient quantity of young *mimosa* (camel thorn) was obtained for the sick camels, and was cut and brought in as required. Other edible shrubs were also utilised.

Arrangements were made for grazing these animals in troops whenever the military situation would admit of it.

The arrangements for watering the animals, both at Suakin and at the advanced posts, were well conducted. The water was sufficient in quantity, and on the whole, of fairly good quality; but that in some of the wells was slightly brackish. The water troughs were frequently inspected, and any suggestions with reference to sanitary improvements met with immediate attention.

The average number of horses, mules, camels, and bullocks, actually employed with the Field Force from the 14th March to 14th May, 1885, is as under:

Horses (including charges)	2604
Mules	3232
Camels	6650
Bullocks	300
Total	12,786

This total does not include the ponies belonging to officers, natives, etc., which would probably bring the average number up to about 13,000.

As regards the quality of the English horses belonging to the British Cavalry Brigade, Royal Horse Artillery, Royal Engineers, and Transport Companies, very little need be said, as they were fair specimens of the class of animal seen in each particular arm on home service.

With respect to their suitability for campaigning in a climate like that of the Eastern Soudan, under the peculiar conditions of desert warfare, I am of opinion that had the military operations been extended, and continued through the summer months, the sickness and mortality amongst the English horses would have been very great. The Royal Horse Artillery, and draught animals generally, kept their condition very well the whole time, and they were comparatively free from sickness; but except in two or three instances, such as the advance to Tamai, they were never subjected to severe exertion, and being at or near the base, were always within reach of suitable food, shelter from the sun for their sick, and good water. The British Cavalry, on the other hand, were more or less continually on the move, especially the detachments at the advanced posts, and the result was that they lost condition rapidly, many of them becoming very emaciated. The percentage of sickness was considerable, and an unusual number of cases of sore back occurred amongst the horses of both Cavalry regiments.

Amongst the horses may be included Egyptians, Indians, "Walers," and a few Syrians and Russians.

The first class consisted of useful and generally well-bred animals, principally purchased in Lower Egypt for the use of Mounted Infantry, and were, in my opinion, extremely suitable for the class of mounted work required in desert warfare. These horses were nearly all entire, as a rule about 14 to 14.3 hands high, and sufficiently strong and hardy to perform the work required of them. They certainly endured the hardships and climatic influences to which they were exposed remarkably well.

The Indian native-bred horses and "Walers" used by the 9th Bengal Cavalry, appeared to do their work without materially suffering in condition, although they were somewhat "fine drawn" at the end of the campaign.

The remarks with reference to the Egyptian horses apply equally to the few Syrians employed. The Russian horses were fortunately very few in number. They were, as a class, coarse, under-bred and comparatively useless animals.

The transport mules were procured from various districts in Lower Egypt, Cyprus, Gibraltar, Malta, and India, and require no special classification; for, with the exception of some unfortunate purchases—animals either too young, or of extreme age—they were strong, hardy, and useful for either draught or pack work, and, as a rule, they kept their condition throughout. I would make special mention of the excellence of the mules employed with the Royal Artillery. I am very strongly impressed with the superiority of mule over camel transport, in any country where even a moderate water supply can be ensured.

The camels purchased for service with the Suakin Field Force may be briefly divided into three classes:

1. The Delta camels purchased in the various districts of Lower Egypt.
2. The desert camels from Berbera and Aden.
3. The Indian camels.

I regret to say that my remarks with reference to the first-class must be anything but satisfactory. A very large proportion of the camels purchased in Lower Egypt were inferior in quality, deficient in size and power, either too young, too old, or otherwise physically unfit, and very many were suffering from (mange) and bad sore backs, on arrival at Suakin. The condition of these animals may in some measure be accounted for by the fact that a considerable number of them were purchased without the advice and assistance of a competent veterinary surgeon. The Delta camel in its own country is, as a rule, freely and regularly watered, and at certain seasons is well supplied with green food. Consequently, at its best, this animal cannot be considered as being so well suited to the requirements of a

campaign in a country like that of the Eastern Soudan, as the ordinary desert camel.

The sickness and mortality amongst the camels from Lower Egypt considerably exceeded that of any other class.

2. The Berbera and Aden camels are smaller, lighter and more active animals than those just referred to, and although they are unable to carry the same amount of weight, this is, in some measure, compensated for by their increased powers of endurance. This is an important feature in a country where both water and green food are scarce. The small fawn-coloured Berbera camels with the Field Force, did their work satisfactorily, and appeared to be well adapted for campaigning in the desert.

3. Indian camels. The transport camels imported from India were strong, useful, healthy-looking animals, and appeared to have been selected with care. They were not so active as the desert camels, but were able to carry more weight. They were much more hardy than the Egyptian camels, and suffered from sickness in a less degree.

Five hundred Sowari camels were procured from India, for the formation of a riding camel corps. In point of conformation and general physique, these animals were splendid specimens of their class, and were able to carry their double loads with the greatest ease, at a very fair pace.

Bullock transport was employed only by the Indian Contingent at the base operations, and about 300 "byles" were used for this purpose, and were worked in light country carts. These animals were sound, useful beasts, of a good class, and did the work they were called upon to perform with ease; but this class of animal is not suitable for either wheel or pack work in the desert, where scarcity of water, absence of green food, the nature of the country, etc., are all opposed to the success of bullock transport.

In submitting the following remark on the working of the Veterinary Department of the Indian Contingent, I beg to observe that its undoubted success was, in my opinion, in a great measure due to the favourable conditions of the military operations, which allowed of sufficient concentration of the mounted troops and transport animals, to enable a zealous and energetic Veterinary

Officer to make daily inspections, and to have his large and important charge under his immediate control: and was not due to a system which, under less favourable circumstances, might have resulted in failure.

The following return of animals submitted on the 7th April, represents about the average number employed with the Indian Contingent:—

Horses and ponies	828
Mules	1896
Bullocks	302
Camels	6
Total	3032

It will be noticed that the value of mule transport was fully recognised by the Indian authorities.

Veterinary Surgeon (First Class) Rayment, was in sole charge of this force, assisted by the following establishment of native farriers, etc.:—

Chief salootrie	1
Assistant Salootries	14
Nalbunds	19

In addition to this staff, a furrier sergeant was employed as veterinary store keeper and dispenser. The whole of the medicines, stores, instruments, shoes, nails, etc., were supplied by the Indian Government, and were ample for all requirements. Each squadron of Bengal Cavalry, and each transport salootrie, was provided with two field medicine chests complete, in addition to the regimental chest. Mr. Rayment had also a six months' supply of reserve medicines in store.

I consider that the veterinary duties connected with the Indian Contingent were very efficiently performed.

The horses of the New South Wales Artillery were under the immediate veterinary charge of Mr. Willows, a colonial veterinary surgeon, who was amply provided with medicines, stores, shoes, nails, and all the necessary appliances. The animals were mostly strong, useful horses, but, as a rule, were deficient in quality.

The following table shows the number of cases admitted to treatment during the campaign, together with the result, calculated, for the sake of convenience, up to the 31st instead of the 14th May, 1885:—

Description of animal.	No. of cases admitted.	No. of cases discharged.	Cured.	Relieved.	Incurable.	Died.	Destroyed.	Remaining.
Horses	648	595	332	188	3	40	32	53
Mules	724	583	468	4	...	86	25	141
Camels	1872	1852	947	440	...	282	183	20
Bullocks	85	79	76	1	2	6
Total	3329	3109	1823	632	3	409	242	220

The unusual number of cases shown in the column "relieved," is due to the fact that many of the animals under treatment for slight injuries were embarked on the reduction of the Field Force, before being quite fit to be discharged "cured."

Amongst the cases shown in the column "died," are included 23 horses and 78 mules killed at Hasheen and in the action at the zereba on the 22nd March. The loss of camels at the latter engagement, estimated at between 800 to 900, is not included. Two horses killed at Tamai on the 3rd April, were accounted for amongst the deaths. The animals shown as "destroyed" were all

affected with disease, or were suffering from accidents of an incurable nature.

Four cases of glanders and one of farcy occurred amongst the horses of the 5th Lancers during the campaign; but owing to the exertion of the executive Veterinary Officers, and to the prompt action taken by the military authorities in carrying out the urgent sanitary measures suggested, the disease was not allowed to spread. No other description of contagious malady occurred amongst the horses during the campaign.

Diseases of the digestive organs were few, and readily yielded to treatment. Respiratory affections were more

frequent, but not sufficiently so as to call for special remarks. Bilious and climatic fevers were prevalent, especially amongst the English horses; but as these cases were promptly detected and treated, the mortality was very small. Wounds, contusions, and lameness from various causes, were not unusually frequent, and were, with the exception of gunshot injuries, of the ordinary character generally met with. Gunshot wounds of various degrees of severity, were more or less numerous during each action, and received the prompt attention of the executive Veterinary Officers, both in the field and in hospital. Several successful operations were performed for the removal of bullets. A number of spear wounds also occurred and were successfully treated.

In a former portion of this report I referred to the numerous cases of sore back occurring amongst the horses of the Cavalry Brigade. Sixty-two cases in the 5th Lancers and 23 in the 20th Hussars, were admitted during the month of April. I consider that many of these might have been prevented, had the folded blanket been used instead of the numnah, which was not sufficient to prevent saddle pressure in those instances where muscular wasting occurred from loss of condition.

The cases occurring amongst the mules were comparatively less numerous than amongst the horses, and as they were generally of the same character, special comment is unnecessary.

A number of mules were hamstrung by the Arabs in action. Some of these cases recovered.

No disease of a contagious character was reported.

Scabies (mange) was very prevalent amongst the camels during the earlier portion of the campaign, and was of a highly contagious nature. The steps taken for the detection and suppression of this disease were fully explained in my remarks on the "Lazaretto Camel Zereba," in a former part of this report. The majority of the cases were successfully treated, and the affection eventually stamped out.

An outbreak of enzootic catarrhal fever of a severe form, occurred amongst the transport camels during the month of April, and many hundreds of animals were affected. In the treatment of this disease the energies of the veterinary surgeons in charge were severely taxed, and had it not been for the able assistance of some of the Indian Transport Officers commanding sections, who promptly superintended the carrying out of the various directions with reference to segregation, medicinal and dietetic treatment, watering and general hospital management, the successful termination and ultimate suppression of this disease might have been a much more difficult matter. Arrangements were made for boiling the food, which consisted principally of grain, bran, tibben, and green camel thorn.

Amongst general diseases may be enumerated respiratory and digestive diseases and non-contagious skin affections, exhaustion and simple fever, together with numerous severe wounds and injuries. Some of the latter were very extensive, and numbers of camels were rendered inefficient, owing to the culpable negligence on the part of camel drivers and others, in failing to report cases of sore backs and injuries until the wounds had assumed such serious proportions as to call for severe surgical operations. Many animals were thus rendered permanently unserviceable.

The diseases amongst the transport bullocks were of so simple a character, and the animals were so few in number, that special remark is unnecessary. No diseases of a contagious nature existed.

The necessary arrangements for the prompt treatment of gunshot and other wounds and injuries occurring in action were made, and each executive Veterinary Officer was amply provided with medicines and appliances for use on emergency. Mules or camels were provided for the transport of field medicine chests; and during the

latter part of the campaign, each farrier sergeant was supplied with one of the new veterinary field wallets.

With the view of increasing the efficiency of the Veterinary Department, and of the Service generally, in future campaigns, I beg briefly to submit the following recommendations for your consideration:

1. That arrangements for the formation of a reserve corps of farriers and shoeing-smiths should be made. This is a subject deserving of immediate attention. Casualties on Service from wounds, sickness, and other causes, the formation of new corps, and the establishment of hospitals and remount depots, all point to the urgent necessity which exists for the formation of a reserve staff of farriers. These men should be immediately under the supervision of the Senior Administrative Veterinary Surgeon.

2. That one or two horse ambulances be provided for service with each Army Corps taking the field.

3. That arrangements should be made for the despatch of veterinary medicines and stores, shoes, nails, pack-saddle forges, etc., sufficiently early to ensure their being at the seat of operations when required for use.

4. That a qualified Military Staff Clerk should be sent out with each Administrative Veterinary Officer, and that the necessary supply of official books, stationery, etc., should be embarked on board the same ship.

5. That each veterinary surgeon should be provided with a soldier-servant prior to embarkation.

6. That, if possible, no Veterinary Officer under 12 months' service be sent on a campaign.

7. That every mounted corps should be provided with the Veterinary History Sheets of its horses on embarkation. Considerable inconvenience was experienced during the military operations by these documents, in many cases, being left in England.

8. That a certain proportion of men per troop of Cavalry, battery of Royal Artillery, or Company of Commissariat and Transport Corps, should be thoroughly instructed in "cold shoeing," and that, when qualified, the names of those men should be registered, and their efficiency tested from time to time.

9. That no transport or other animals be purchased for service, without being previously inspected by an Officer of the Army Veterinary Department.

10. That arrangements should be made to supply the necessary material for temporary shelter from the sun, in the case of English horses being engaged on active service in a tropical climate. Poles, with mat or canvas screens, answer this purpose very well.

11. That blankets should be provided for all mounted troops, to take the place of numnahs on active service. However well a saddle may fit when the horse is in good condition, the protection of the numnah is insufficient to prevent its "coming down" upon the back, in cases where muscular wasting takes place as the result of the hardships consequent upon a campaign.

12. That in cases where camels are used with an army in the field, the services of experienced officers, such as those belonging to the Indian transport, should be engaged, and that none but qualified drivers should be employed.

The value of this suggestion was proved by the experience of the late campaign. The condition, health, and general efficiency of the animals belonging to corps commanded by officers well skilled in camel management, was most marked; and from personal observation I am convinced that this important subject is well worthy of the serious consideration of the authorities.

That the camel is a delicate and peculiarly constituted animal there can be no doubt; and we know that, in order to ensure efficiency and to avert serious loss to the public, the various details of dietetic management, distribution and arrangement of loads, inspection and fit-

ting of saddles, grooming, and other minor but important items, must be attended to and carried out under the personal observation and supervision of experienced officers.

In conclusion, I take this opportunity of expressing my sense of the cordial support and assistance received at all times, during the campaign, from the various military authorities, which so greatly facilitated the smooth working of the department.—I have, etc.,

W. B. WALTERS,

Principal Vety. Surgeon to the Forces in Egypt.

ASSOCIATION OF VETERINARY OFFICERS OF HEALTH.

The annual meeting was held in the Caledonian Station Hotel, Edinburgh, on Friday, October 13th, the President, Mr. William Robb, F.R.C.V.S., Glasgow, presiding. County and burgh local authorities in all parts of Scotland were represented, and there were also English representatives from Hull, Newcastle, Bradford, and Sheffield. Amongst others present were Captain Gilmour, M.P., and Prof. Gofton, of the Royal (Dick) Veterinary College.

PRESIDENTIAL ADDRESS.

WILLIAM ROBB, F.R.C.V.S., Glasgow.

It is my privilege as your President to introduce Prof. Delépine and Mr. John Lindsay to you, and I feel satisfied that I give utterance to your wishes when I tender to them a warm welcome, and a deep appreciation of the honour we are receiving by their addressing us today. It is not my intention to detain you by a long address, but, with your permission, I would like to address you for a few minutes on the position of meat inspection and meat inspectors in this country.

It is undoubtedly a fact that meat inspection is now on a much sounder basis than it was a few years ago, but I feel confident that no one present will say that our methods and regulations compare at all favourably with those of our Continental neighbours.

Take the varying conditions that exist in most counties. First of all, you have the large city with whole time inspectors, now, in many instances, under a veterinary officer. A few miles out you find the village butcher with a slaughterhouse behind his shop, and generally no inspection. Proceeding a few miles further on is a country town with a lay inspector, frequently under the supervision of a veterinary inspector who is not a whole-time officer.

Undoubtedly the ideal conditions are those of the large cities, where the inspectors are free from private practice and devote their whole time and attention to this special subject, the animals being slaughtered in public abattoirs. While it may be true that many splendid animals are dressed in private slaughterhouses, it is against the ideals of modern standards of meat inspection that private slaughterhouses should exist, with or without inspection.

As you are no doubt aware, foreign Governments have drafted regulations for the guidance of their meat inspectors, so that the standard will not vary in almost every town. Compare that with the chaotic condition of matters in this country. What are the regulations drawn up in this country for the guidance of meat inspectors? Nothing but the finding and recommendations of the 1907 Commission on Tuberculosis. These findings, remember, deal only with tuberculous carcasses, and no other affections or conditions. Now, let me ask you, are the recommendations of that Commission strictly adhered to by meat inspectors in this country?

In my opinion they are not, therefore is it not high time something was done in the way of drafting regulations, more in keeping with modern knowledge and opinion, dealing not only with tuberculous carcasses, but also with other diseases and conditions that render meat unfit for the food of man.

This we, along with other representative bodies, have asked the Local Government Board of Scotland to do, also that a veterinary officer be appointed to its staff. Unfortunately it was not thought fit to make such an appointment, nor was it believed that it had the power to draft recommendations dealing with meat inspection for the guidance of meat inspectors.

It does seem a strange thing that a veterinary surgeon is considered qualified by many local bodies to examine meat intended for human consumption, and that the Local Government Board is not yet prepared to appoint one to supervise the work throughout the country. While our position is assured under the Public Health Act, 1907, it will be found, as pointed out recently by Prof. Hay, M.O.H. for Aberdeen, that in the various regulations recently issued by the Local Government Board, the medical officer was the only officer specially named, and that all certificates for exported meat could be signed by him only.

What is the explanation of this condition of affairs? We are recognised by an Act of Parliament, yet in regulations drawn up by the Local Government Board we are ignored. How this method of granting certificates by the medical officer works out in practice I will leave it to others to explain.

It seems to be a matter of opinion as to whether a medical officer or a veterinary officer should have charge of the inspection of animals intended for the food of man. The number of medical men who claim the sole right to this position I believe to be getting gradually less, but in case there be any of my professional brethren present who believe the medical officer's claim to be absolutely dead, permit me to read the following opinion. It would seem that recently there had been an idea amongst some members of the Town Council of Aberdeen that it might be expedient to appoint a veterinary surgeon to act as meat inspector, and naturally the opinion of their medical officer, Professor Matthew Hay, was taken. From *The Medical Officer* I cull the following excerpt:—"Dr. Hay claimed that, in any case, the real question to be settled in the inspection and seizure of meat was whether the meat was fit for the food of man, and whether the disease was communicable to man. The standards, he writes, 'fall to be determined by the answer to this question, and the answer could properly be given only by those who had made a study of human diseases, and of their etiology.' Happily friction was avoided by the appointment of an additional lay inspector to work along with the previous inspector, under the direction of the medical officer and sanitary inspector.

Far be it from us to claim that we have made such an exhaustive study of human diseases as a medical officer has naturally had to do. Our claim is simply that we have made a study of the diseases in animals that are communicable to man, and from our training are better qualified to judge of abnormal conditions in the lower animals.

The opinion quoted above—as to why a veterinary surgeon should not be appointed to assist in carrying out the terms of the Public Health (Scotland) Act, 1907—is that of a medical officer to a great city—of a city where 40,750 cattle and 42,000 other animals are killed annually, with several slaughterhouses under the supervision of one lay inspector.

To show that all medical men do not hold the views of Professor Matthew Hay of Aberdeen, permit me to quote from an article recently written by Professor

McWeeney, of Dublin, on meat poisoning. Professor McWeeney is a man who has come into close touch with our profession, not only with the qualified man but also as an examiner for the diploma of the Royal College of Veterinary Surgeons. He writes: "It is at the slaughterhouse that such conditions as anthrax, blackquarter, pneumo-enteritis, swine erysipelas, and Gaertner infection can be most readily and certainly diagnosed by the aid of bacteriological procedures that can be efficiently performed by the well trained young men now being turned out by our veterinary colleges."

Personally, I feel confident that in time, as these posts fall vacant, or as public bodies become educated to the vast difference that exists between the man who has made a study of human diseases, and the man who has made a study of animal diseases, especially those communicable to man, we will see a change in the type of man appointed to supervise meat inspection.

Municipal bodies and the public are bound in time to recognise the difference between the man who sits in his office, making up monthly and yearly reports, based on facts and figures supplied by the real inspectors, and the man with an intimate knowledge of this special subject, regulating, guiding, and checking the work of his subordinates by personal supervision.

It was agreed that next meeting should be held in Perth, and Mr. J. G. Reynard, M.R.C.V.S., of that city was chosen president.

After the conclusion of the formal business a paper on "Tuberculosis and the Milk Supply" was read by Prof. Delépine, of the Public Health Department of the Victoria University, Manchester. Having outlined past work in investigating tuberculosis, and referred to the appointment of the Royal Commission on the subject, the Professor said they could accept as proved that bovine tuberculosis was a serious source of danger to man, and that of all bovine tuberculous products tuberculous milk was the most dangerous, owing to the share it took in the feeding of infants. That tuberculous infection of man by man was more common than infection of man by cattle was no reason why one should postpone dealing with bovine tuberculosis till all human sources of infection had been dealt with. The special methods which afforded a measure of protection to man were quite insufficient to protect cattle against the spread of the disease. The reverse was not true, for if bovine tuberculosis were stamped out by general measures the sanitarian would have nothing to fear from tuberculosis of cattle. The eradication of bovine tuberculosis was, therefore, a subject in which the hygienist was keenly interested. Referring to the methods which had been recommended for the sole object of protecting human beings against the effects of the consumption of tuberculous milk, he stated that the boiling of milk fulfilled this purpose efficiently, and as long as tuberculous milk and meat formed a necessity and considerable part of our diet their sterilisation would remain a necessity. Pasteurisation of milk as ordinarily carried out was not, in his opinion, an absolute safeguard. The infectivity of milk, if not entirely removed, was undoubtedly considerably reduced by this process; but he had found by careful experiments that living tubercle bacilli capable of infecting sensitive animals were sometimes present in milk and in cream which had been carefully pasteurised by accepted methods. The same was true of rapid desiccation by heat even when superheated steam was used for the purpose. The removal of slime by centrifugalisation, though good in itself, reduced to a moderate extent only the infectivity of milk. He did not think that any method based upon chemical treatment could effectively destroy the bacilli without rendering the milk unfit for use.

The lecturer referred in some detail to microscopical

and bacteriological tests, cultivation tests, and inoculation tests as methods for ascertaining whether milk was infectious or not. He thought he was justified in saying that they were all unsatisfactory when employed for the purpose of controlling directly the sale of milk. He would go further and say that even if an almost instantaneous test were discovered by which the presence of tubercle bacilli in milk could be infallibly detected, this method would not solve the difficulty in a satisfactory manner. In the first place, the infectious material would continue to be distributed as long as the examination of a sample had not revealed its existence. Secondly, the only effect of the testing would be either the exclusion of the contaminated supply from a certain market and its diversion to another, or, if all the markets were closed to tuberculous products, the farmer, being left unguided, would, in the present state of things, be exposed to such losses that the dairy industry would suffer greatly. This method of control of tuberculous milk would therefore afford only partial protection to the consumer, and would seriously damage the dairy industry unless the farmers were at the same time helped to put their herds in order. This difficulty might, however, be partly overcome by a combination of the testing of milk with the inspection of farms. It had been suggested that resistance to tuberculous infection could be so increased by improved social conditions (including good feeding, proper housing, and good sanitation) as to render the chances of infection slight. It was quite true that poor, weak, ill-fed individuals, crowded in unhealthy dwellings, were much more liable to suffer from exposure to infection than others; but he did not believe that simple sanitary and hygienic measures—valuable adjuncts though they were—could overcome the danger of infection by massive doses of infecting material, and, more especially, that infants could be protected in this way from the effects of feeding on tuberculous milk.

The unsatisfactory character of the methods which he had outlined indicated the advantages which, even from an ordinary public health point of view, the eradication of tuberculosis in cattle would have. The task was, however, one requiring cautious consideration on account of its magnitude, and of the financial difficulties which it involves. The method of control at present in use in Manchester was devised for the purpose of protecting the town against the importation of tuberculous milk from the country. The Borough authorities had for a long time been able to control the farms and dairies within its boundaries, but up to 1899 were unable to influence adequately the rural districts from which the bulk of the milk supply was derived. Their preliminary investigations conducted before that date had shown that the rural supply was highly infected. Although personally convinced that general measures would ultimately be found to be the only satisfactory method of prevention, he had from the first done his best to assist Dr. Niven in the carrying out of the policy which he considered to be the only one possible, under the circumstances, for the protection of the town under his care. Under the scheme, samples of the mixed milk coming from various farms were collected at the railway stations or elsewhere within the city, by the food and drug inspectors. These samples were sent to the bacteriological laboratory for examination. Any farm found to send milk causing tuberculosis by inoculation was inspected by the veterinary surgeon, who examined all the cows on the farm and took a sample of milk from each cow having a diseased or suspicious udder. These samples of unmixed milk were tested by inoculation at the bacteriological laboratory. The medical officer of health requested the farmer (1) to isolate the cows yielding tuberculous milk; (2) to cease sending the milk of these cows to town; and (3) he advised the farmer to have the cows with tuberculous udder slaughtered in the presence of the veterinary surgeon of the Corpora-

tion. This advice was followed in a great number of cases. The final step consisted in taking one or more samples of the mixed milk of the farm or shippin from which one or more cows yielding tuberculous milk had been removed. If these control samples were proved by bacteriological examination to be incapable (in the quantities used for the test) of producing tuberculosis, the farm was considered for practical purposes and for the time being free from sources of tuberculous infection capable of rendering the milk dangerous. If the control samples produced tuberculosis the farm was inspected again until all cows secreting tuberculous milk had been removed. The administration of the Manchester milk clauses had had a very marked effect upon the state of the farms supplying milk to Manchester. With one slight break in 1903, the improvement had been very steady, and at the present time the number of farms producing tuberculous milk was less than one-half of what it was in 1896 to 1900. This improvement had been effected (1) by the enforced removal of cows suffering from tuberculosis of the udder, which generally were also affected with advanced tuberculosis of other organs; (2) by the voluntary removal of many other diseased animals as a consequence of the knowledge acquired by the farmers as the result of the inspection of farms in their district by competent men; (3) by a general improvement in the sanitation of farms that had come under the control of the authority, and a better knowledge on the part of the farmer of the circumstances favouring the infection of stock.

A less satisfactory consequence of this improvement of the Manchester supply had been the transfer of suspicious cattle from farms under inspection to farms sending their milk to places which did not control their milk supply. In several cases also, farmers who supplied tuberculous milk to Manchester had, when this was discovered, ceased sending milk to the town, and now send it elsewhere, or use it to make cheese. Under this system, therefore, the benefit gained by the more enterprising community became a source of danger to its less active neighbours. This was true even though the Manchester authority endeavoured by all means in its power to supervise the disposal of infectious animals so as to cause their entire removal. The returns relating to the milk supply of Warrington were very instructive in this respect. In 1909 Dr. Coote Hibbert, the medical officer of health, urged on the Warrington authority the necessity of controlling the milk supply of the town more efficiently than had been previously done. In April, 1910, he began to send samples of milk to his (the lecturer's) laboratory, and to inspect farms found to supply tuberculous milk. Between April, 1910, and September, 1911, 115 samples of milk coming from 69 different farms had been tested, with the result that 11 were found to contain tubercle bacilli. In order to realise the state of things in April, 1910, and the effect which the inspection of farms and the removal of tuberculous cows had had upon the Warrington milk supply, it was necessary to divide the period of eighteen months, over which the work had extended, into three periods of six months each, and to compare the state of the mixed milk and of the farms during the three periods. The results of this comparison showed (1) that eighteen months ago the Warrington milk supply was more extensively infected than the Manchester milk supply had ever been between the years 1896 and 1911; (2) that after only six months' inspection work the Warrington supply had become as good, if not better, than the Manchester milk supply. The remarkable success obtained in this case was, in part, due to the smallness of the area, which made close supervision of the farms comparatively easy, but the rapidity of the change suggested the voluntary removal by the farmers of some suspicious animals. From the wider point of view which should be taken by the statesman it would appear,

therefore, that the isolated municipal control of the milk supply had serious defects. Yet it was clear that, so long as the State remained passive, it was the duty of enlightened communities to protect themselves against every possible source of disease. The policy adopted by Dr. Niven in 1899 was undoubtedly the right one under the circumstances, and it had on the whole been very beneficial and instructive, not only to the Manchester citizens, but also to a great number of farmers. Nevertheless, the facts he had related indicated clearly the need for more general measures having for object the stamping out of bovine tuberculosis. Although municipal authorities had a right, for their own protection, to see that the needed work was efficiently done, it was clear that much of what had to be done was entirely out of their sphere of action. It was equally clear that small urban districts would not be able to carry out efficiently work such as had been done in Manchester, so that, if all the large towns succeeded in purifying their milk supply it was probable that much of the milk refused by them would finally be supplied to the smaller towns.

In the latter part of his paper the lecturer discussed the question of the eradication of bovine tuberculosis, referring in some detail to the French system (Nocard and others, 1888); the Danish method (Bang, 1893); and the Prussian method (Ostertag, 1900). His objection to all these methods was that they did not provide (1) for an efficient supervision by competent men of every beast in every district; and (2) for the prevention of the frequent recurrence of sources of infection. The incompleteness of the results obtained by such methods, and the magnitude of the cumulative expenditure caused by this failure, would, he believed, in the end discourage the farmers and the authorities, and make them overlook the beneficial effects which partial measures undoubtedly produced, because these beneficial effects would be insufficient to secure permanent benefits. These considerations led him to devise the system which he first outlined in 1897, and which he had advocated on several occasions since. That system was, briefly—

(1) Division of the whole country into a number of well-defined administrative areas, each provided with an efficient staff of veterinary inspectors.

(2) Marking and registration of all cattle for purposes of inspection and notification. (This would, of course, mean the inclusion of tuberculosis among the recognised contagious diseases.) Systematic periodical inspections of herds and cowsheds within each administrative area. Testing with tuberculin of all cattle.

(3) Isolation of all tuberculous cattle. Disinfection of sheds which have been occupied by tuberculous cattle.

(4) Immediate slaughter of all cattle in an advanced state of tuberculosis (including all cases of udder tuberculosis).

(5) Fattening of all animals not in an advanced state of tuberculosis for the meat market. All cattle should be slaughtered in public abattoirs, so as to ensure thorough meat inspection.

(6) Compensation during one year or two for losses incurred by owners of cattle, except in cases when there had been gross or culpable neglect. After this transitional period of compensation the presence of a case of advanced tuberculosis in a cowshed to render the owner liable to a penalty.

(7) Testing of all cattle brought into the area, so as to prevent the introduction of fresh sources of tuberculosis. No cattle above six years of age to be imported.

(8) All the milk from tuberculous cattle to be boiled before use.

(9) Control of all foreign dairy produce, so as to enforce the same standard of purity as in the case of home produce.

(10) To avoid a sudden national depression in the dairy industry, the enforcement of these measures

should not be simultaneously carried out all through the country, but they should be at first enforced in a certain number of well-demarcated administrative areas, to which, year after year, other districts should be added, until the whole country was under administrative control. It is probable that the work could be accomplished in some five or six years.

The chief difficulty connected with this plan was, as in the case of the other methods, the financial one. This under the system would be temporary only, with, however, the exception of the expenditure caused by the establishment of an efficient veterinary service, which would certainly become a permanent institution, for such a service was needed for many other purposes than the eradication of tuberculosis. The first great outlay would be caused by the removal of old cattle in an advanced state of disease. But this first removal would afterwards secure the entire absence of such cattle. He contended that the disposal of young tuberculous animals in which the disease was very seldom advanced could be effected with little loss if these animals were properly fattened before being sent to the abattoir.

A paper on "Existing and Prospective Legislation *re* Milk Supply," was read by Mr. John Lindsay, Town-Clerk-Depute, Glasgow. He remarked that having regard to the fact that milk was an important part of the food of man, and particularly of that of young children, and that it was undeniably the channel by which many serious diseases and illnesses may be carried to human beings, it was surprising that the law had not been uniform throughout the United Kingdom, and that it had not been set forth in the statutes in simple and concise yet comprehensive terms. The law on the subject, contained in many statutes, orders, and regulations, was complex and confusing, in some instances contradictory, and, in a general sense, chaotic. Mr. Lindsay proceeded to submit a succinct statement of the law on the subject. In the course of his remarks he urged that compensation under the Tuberculosis Order of 1909 ought to be provided out of the Imperial funds, and not placed on the local rates. Commenting on defects in the Bills of Mr. Burns and the Secretary for Scotland, he said these were principally caused by the jealousy of local authorities—the county was jealous of the burgh authorities, and would not permit interference on the part of the latter in dairies and dairy farms when the disease was known to break out and to attach to certain milk producing centres. Until in his clear opinion the representatives of the milk consumers in those larger burghs had some immediate say in the methods of its production, and had the power to refuse to take milk which was suspected of producing illness or disease, the whole question of a town's milk supply could not be on a satisfactory basis so far as the citizens were concerned.

DISCUSSION.

In the afternoon a discussion on the papers took place, the first speaker being Mr. Lloyd, Sheffield, who said that he was fully in accord with many of the remarks of Professor Delépine as to proposed legislation, but he was afraid he could not go so far as he went on the matter of finance. He believed that tuberculosis was to be found in dairy produce other than milk. In regard to legislation, he said it was a question how far the public were educated to go, and where the money was to be found. Discussing the second paper, he said that at present notification was practically a dead letter. It must be compulsory, and accompanied by compensation. (Applause.)

Mr. Cameron, Berwick-on-Tweed, said he was not a Home Ruler, but there were some lessons to be learned in these matters from Ireland. (Applause.) Continuing, he said there was only one conclusion to come to,

and that was that the presidents of the Local Government Board were practically ignorant of the subject, and that they had been led by ignorant, selfish medicals, proving unmistakably the necessity for a veterinary member of the Local Government Board. (Applause.)

Councillor Dr. Erskine, Glasgow, believed that local authorities had power to follow up cases from which infection proceeded. He should like to have seen a greater representation of the medical profession at the meeting. He was not at all orthodox as to the views medical men held in regard to veterinary inspection. He believed the day had arrived when this branch of the work should be left in the hands of veterinary men. From their training, clinically and scientifically, they were very much better qualified to deal with tuberculosis in cattle than medical practitioners were. (Applause.) He did not see why the medical profession would not relinquish this department into the hands of veterinary surgeons. It was irritatingly disappointing that they were taking such a long time to get a satisfactory Bill in regard to the control of milk through Parliament.

Mr. M'Phail, Hull, declared that neither John Burns nor the Local Government Board were led by medical men or anybody else. It was a question of party politics. He gave a number of experiences in the working of the various regulations, and thought this matter should be left with the Local Government Board rather than placed under the Board of Agriculture as had been proposed.

Having to leave to catch a train, Prof. Delépine at this point replied on the discussion; and the Chairman, in expressing the thanks of the meeting, requested him to consent to become an honorary member of the Association, which he did.

Mr. Hugh Begg, Lanarkshire County Council, with reference to the statements as to cows found to be infected being removed by the owners elsewhere, said in Lanarkshire every such case was watched by the authorities. Veterinary surgeons could clear this country of tuberculosis with the greatest of ease if they had plenty of money.

Mr. Peddie, Dundee, and others continued the discussion.

Councillor Smith, Glasgow, said the Corporation of Glasgow were not only wanting legislation but wearying for it. They wished some forward movement could be made.

Mr. Lindsay replied to this discussion, and was also elected an honorary member of the Association.

On the motion of Mr. Lloyd, a resolution was adopted calling upon the Government to take immediate steps to control tuberculosis on the lines suggested in the paper read by Professor Delépine.—*N.B.A.*

Cruelty Charge against a V.S. at Wigton—Dismissed.

At Wigton (Cumberland) Police Court on Tuesday, 24th inst., Joseph Donald, a well-known veterinary surgeon, was summoned on the information of Inspector Hampshire, R.S.P.C.A., for causing a cow to be cruelly ill-treated on divers dates on and between September 19 and October 6.

Mr. Stewart Bevan, barrister-at-law, London (instructed by Mr. Sydney G. Polhill, solicitor, London) appeared for the prosecution, and Mr. Joseph Hetherington, solicitor, Wigton, was for the defendant.

Mr. Stewart Bevan said the substance of the cruel ill-treatment was that the defendant kept, and caused to be kept for a considerable period, a cow which was wholly deprived of the use of one of its forelegs under such conditions as to cause intense distress and considerable pain to the cow in living in a field and moving about

in its attempt to find food and get water. Mr. Donald was a veterinary surgeon, and as the Bench would see from the evidence an attempt was made to avoid what was always a disagreeable duty, namely, prosecuting a member of the profession, who the Society looked to in assisting them to enforce the law with other people in regard to cruelty. It was something like obstinacy on Mr. Donald's part, for when his attention was drawn to the condition in which this cow was existing, and he was asked to remedy things, he refused to do so and told the Society's Inspector to make a case if he could. The Society were therefore obliged to issue a summons.

The cow's front leg was drawn up from the knee and it was unable to use the leg at all, was in a very poor and distressed condition, and bringing the whole weight of the fore part of its body upon the near fore leg: the leg was flexed upward—there could be no downward movement. Its sufferings did not end there for there was a young bull in the field and two young calves which interfered with it. He said it was the duty of everybody, and more particularly he should have thought of a veterinary surgeon, who was more familiar with what was more likely to cause suffering to an animal, when he had an animal in such a condition as that, not to place it in an open field to look after itself, but to put it in a place and, if necessary, sling it to prevent it being in pain, and bring food to it and keep it under conditions which would reasonably alleviate the suffering of the animal.

John Wilkinson, photographer, High Street, Wigton, who took a photograph of the cow at the request of Inspector Hampshire, now produced prints of it.

Inspector Hampshire, R.S.P.C.A., said he first saw the cow on Sept. 18 in the field when passing in the train. It was making spasmodic jumps to get along. On the following day he went to the field and found that the cow was going on three legs, and was in very poor condition. She had a wild look about the eye, and could only walk with difficulty. He examined the deformed leg and found that she could not flex it. Locomotion did not come easy to her, and in his opinion she was suffering both pain and discomfort. There were two calves in the field and as soon as the cow got up they went to her and began to butt her in the udder, and try to force milk to flow. A young bull that was also in the field annoyed her and she laid down. The bull was about 14 or 15 months old. The bull and calves seemed to irritate the cow. Witness afterwards saw the defendant and told him that he had seen the cow, which seemed to be in an awful state and very lame, and that there was a young bull and two calves in it to worry her. He told defendant that he did not think she ought to be there at all. He said, "Why?" and witness replied that the cow was in pain—that it was evident to anybody. Defendant said, "Well, I do not think so," and witness replied, "I must differ with you, Mr. Donald, although you are a veterinary surgeon." Defendant said "Well you know the cow is in no pain, and you can do what you like." As the defendant spoke abruptly, he left him and took him at his word. He had the cow photographed by Mr. Wilkinson. On Sept. 25th he again went to the field in company with Mr. Malloch, V.S., Kirkby Stephen, who examined the cow. The conditions were about the same. There were three feeding troughs lying on the grass, and one was upside down. There were no marks of any kind to show that the troughs had been used for feeding the animals, and he could not find any evidence of food having been brought. They searched the field for a water supply, and found that there was a small beck at the bottom of the field, to let to which the cow would have to go down a steep bank. She would suffer a great deal of pain going down and coming up the bank, and he did not think she would go down unless she was actually forced by thirst to go there. On October 2 he again visited the field and found that things generally

were in the same condition. The feeding trough showed no indication of having contained food. There was no alteration in the conditions on the occasion of his visit on October 6.

Cross-examined: When he took out the summons he followed the usual course. It was not usual to state on the summons the manner in which the cruelty was caused.

Mr. Hetherington said that the summons did not state in what manner the cruelty was caused, and it left it open for the prosecution to allege any acts of cruelty they liked when they came into Court.

Cross-examined by Mr. Hetherington, the Inspector said that no complaint was made to him about the cow. His first examination was a visual one. He thought that withering away was evidence of the existence of pain. He did not see the cow lick herself. The cow was suckling two calves, and that would make a difference in her condition. The calves were in fairly good condition and so was the bull. He would not say there was plenty of grass. He believed the cow had suckled four calves. He had asked three veterinary surgeons in Cumberland and one in Northumberland to examine the cow but they refused to do so.

Re-examined: There was a natural reluctance among many professional men to give evidence against another member of their own profession.

Alfred Kershaw, M.R.C.V.S., Southport, said he had had 27 years experience in the middle of an agricultural district. On October 6th he examined a roan cow shown to him by Inspector Hampshire. When he went into the field it was lying down, and the first thing he noticed upon it rising was its miserable appearance. Its coat seemed to be rather harsh, and it had a dull expression in its eye. From the condition of the ground it appeared to have lain about four hours. In the off-fore leg, all the muscles of the fore arm were completely wasted away, and the lower portion of the limb was at right angles to the knee. The limb could be drawn up but it could not be depressed, and it was of no use to the cow in moving about. It was quite evident that she must have been lame for a long time as the result of a fracture. There would be a certain amount of pain on rising, and the condition of the animal pointed to the conclusion that it was being cruelly ill-treated by being kept under such conditions. It would be difficult for the cow to get to the water, and it would be only with great compulsion that she would go. He saw the two calves in the field, and also a bull hanging round and paying her unwelcome attention. The cow had no milk in her udder. Assuming there was no local pain in the leg the animal was not fit to be turned out into the field. It was an act of cruelty to keep it under, what he considered, disgraceful conditions. There were no signs of food having been brought to the feeding troughs, which appeared to have been undisturbed for a long time.

Cross-examined: There were indications of pain because she flinched under extreme pressure. The only sign of local pain he saw on his examination was in the injured limb when the cow attempted to rise. It would not be constituted cruelty if she had been kept inside under better conditions. An animal suffering pain might have a normal temperature and a normal pulse. She would not have any pain when she was in a recumbent position. In case of injuries to the limbs of extremely valuable cattle amputation was resorted to, but it was not so with ordinary milk cows. It was the general conditions under which the cow was living that he objected to.

Re-examined: The animal ought to have been placed in a box and the food brought to her.

Robert M. Malloch, M.R.C.V.S., Kirkby Stephen, who has had 25 years experience, said he examined the cow on September 25th, and found it in a very emaciated condition. It had an anxious expression, and was walk-

ing on three legs, the near fore leg being bent at the knee. A bull was giving her some attention, and she could not get away from it without pain or discomfort to herself. Two calves were butting at her and trying to get milk from the udder, but there was none, and the cow tried to get away best it could. There were no signs of food except grass. It was rather improper to put the cow into the field. It would have been more humane to have tied it up in a stall.

Cross-examined: He took the pulse, which was rapid, and which indicated that there was a certain amount of nervous irritation somewhere. He could not see any signs of good health. The cow had a cough. He did not see any signs of a fracture. The leg would probably have got into the position it had from an injury to the muscles.

William Hunting, F.R.C.V.S., an ex-President of the Royal College of Veterinary Surgeons, in practice in London, said he had seen the cow that morning, and she might have been treated better than had been described. The conditions he objected to were that it had to travel on three legs instead of four, and the difficulty of getting up and down the bank for water. It would certainly add to the discomfort of the animal. The presence of the bull and calves would also add to her discomfort. It was only justifiable to keep a cow like that to get a calf which was valuable, or to endeavour to get it fat for the butcher if it was in poor condition. It would be better in a loose-box than a field.

Cross-examined: He knew that Mr. Donald was one of the examiners of the College. From the conditions under which he found the cow that morning he could not say that it was cruel ill-treatment on the part of Mr. Donald.

George Moffat, signalman, in the employ of the Maryport and Carlisle Railway, said that his cabin overlooked the field, and the cow had been in it all summer. He had never seen any one bring it food or water, and he had seen the cow most days. The cow could not walk, and it had to jump about.

Cross-examined: He had been 20 years in the signal cabin. He saw the cow last summer. He had only seen the bull chase the cow once.

Mr. Stewart Beavan informed the Bench that the cow was not in the same field as it was on the dates included in the summons.

This concluded the case for the prosecution.

DEFENCE.

Mr. Hetherington said that when his friend opened the case and asked the Bench to convict on the evidence he put before them, he had not anticipated that an eminent veterinary surgeon like Mr. Hunting would say that he could not see any signs of cruelty and nothing to justify them in convicting the defendant. It was iniquitous and most improper that a gentleman in the position of Mr. Donald should be called there and put to the expense of defending himself upon the charge. After he called his evidence he was going to ask the Bench not only to dismiss the charge but also to say that it ought never to have been brought. If the case for the prosecution depended upon the evidence of Inspector Hampshire they would have something to go on. But they were followed into the box by two veterinary surgeons about whom he did not want to say anything. In justice to Mr. Donald he must say that the photograph had been hawked about to three veterinary surgeons in Cumberland and one in Northumberland before they could get one to come and give evidence against Mr. Donald. Both the gentlemen who had come were unknown to their fellow practitioners in Cumberland, and upon their evidence, notwithstanding the refusal of the others to come, the Bench were asked to convict Mr. Donald. They had heard from

their evidence the nature of the examination made. One of them, although he was an expert witness, never saw the fracture at all. Mr. Donald, who was well known to the magistrates, had had a long and varied experience in veterinary surgical matters. Did they think for one moment that he was a man who was likely to keep a cow for two summers in a field in a cruel position? Mr. Donald had a reputation, which went far beyond the borders of Cumberland. He had the highest and best qualification known to veterinary practice which could be obtained, and he was recognised upon that by the leaders of his profession as one of the most expert animal surgeons in the North of England. Mr. Hunting was a President of the Council and Mr. Donald was an ex-member of that Council, and had frequently acted as examiner of candidates who were applying for entry to the profession of Veterinary surgery. The Bench were asked to say that with that reputation and experience behind him, defendant put the unfortunate animal into the field and cruelly ill-treated it. The condition of the animal was due to a fracture of its humerus which occurred on July, 1909—two years and four months ago—and it was due to calve early in September. It was a valuable breeding cow, and a valuable dairy cow. What was to be done in circumstances like that? The only proper surgical course and the only humane course to adopt was to attend to the fracture, wait until the cow calved, and then try to do something to cure the inevitable shortening of the leg that must occur after a fracture of that kind. That was exactly the course adopted by Mr. Donald. He attended to the fracture, waited until the cow had delivered her calves in September and they had got well away, and then he tried to cure the cow of her injury. He had two alternatives—either to amputate the leg or perform the operation of tenotomy, by which the injured limb was drawn clear of the ground. There was no reason for the amputation, which would have been a more cruel and painful way, so Mr. Donald in his judgment decided to perform tenotomy. This he did successfully and it left the limb in the position shown by the photograph. The treatment was quite humane. He would call Mr. Ashley, F.R.C.V.S., of Dalston, who also held the highest qualifications, Mr. T. Richardson, Wreay, and Mr. W. H. Williamson, Waverton, and several railway servants, after which he would ask the Bench to dismiss the case.

Without hearing the evidence the Bench retired, and on their return to Court, the Chairman (Alderman Wm. Williamson) said that they had decided to dismiss the case and each party would have to pay their own costs.

Coleman v. Twining—A New Trial.

In the Court of Appeal on Monday, October 23rd, before Lord Justice Vaughan Williams, Lord Justice Buckley, and Lord Justice Kennedy.

This was an application by the defendant for judgment or a new trial in an action tried before Mr. Justice Lush and a common jury, reported in *The Times* of February 27.

The plaintiff, Mr. John Coleman, a veterinary surgeon, sued the defendant, Mrs. Ada Louisa Twining, to recover the sum of £30 4s. 6d. for professional attendances upon dogs belonging to her. The defendant denied liability and counter-claimed to recover damages for alleged negligence by the plaintiff in the treatment of her dogs in consequence of which they became ill and died of distemper. The alleged negligence consisted in putting such delicate dogs as Japanese spaniels into kennels in an open yard, where low temperature made them prone to distemper, and in not sufficiently isolating the dog which first displayed symptoms of distemper.

At the trial the jury returned a verdict for the plaintiff on the claim and counter-claim, and the learned Judge directed judgment to be entered accordingly. The defendant applied for a new trial on the grounds that verdict was against the weight of evidence, and that the learned Judge had misdirected the jury; and in the alternative for judgment.

Mr. Stewart Bevan appeared for the defendant; Mr. Rawlinson, K.C., and Mr. Patrick Hastings for the plaintiff.

The Court ordered a new trial.

Lord Justice Vaughan Williams said that in his opinion the Court could not refuse to grant a new trial. He thought that the learned Judge had misdirected the jury on a material point which might be reasonably thought to have influenced their verdict in telling them that there was no evidence which would warrant them in finding that one dog either got the disease of distemper or showed signs of distemper so many days before the other dogs that they could come to the conclusion that if there had been proper isolation the other dogs' lives could have been spared.

Lord Justice Buckley said that he had with regret and reluctance come to the conclusion that there had been a misdirection just sufficient to entitle the defendant to a new trial.

Lord Justice Kennedy concurred.

Solicitors.—William Easton and Son; Calder, Woods, and Pethick.

From another report:—

The case which had occupied this Court for two sittings is of special interest to owners of dogs, but also

of general interest because of some remarks made by Lord Justice Vaughan Williams, as to persistency in incurring legal expenses upon comparatively trifling matters.

In the course of the proceedings a model of the kennels was produced, and Mr. Bevan proceeded to argue the question of isolation in this form of disease.

Lord Justice Vaughan Williams asked what distance from other unaffected dogs constituted effective isolation.

Mr. Rawlinson: One expert said a quarter of a mile. (Laughter).

Mr. Bevan submitted that, taking into account the period of incubation, the animals were not isolated soon enough.

At the close of Mr. Rawlinson's argument against the appeal, the Court gave judgment allowing the appeal, on the ground of misconduct. They ordered a new trial, and also directed that a sum of £400 paid into Court by Mrs. Twining in respect of the first trial be refunded. Appellant was given costs of her successful appeal, and the cost of the first trial will abide the result of the second.

Lord Justice Vaughan Williams expressed a hope that the parties would not go to a second trial and incur more expense, but that they would allow a friend to act as mediator, with a view to a mutual agreement. This course was all the more advisable because there was not now any imputation upon the general or professional skill of Mr. Coleman. It seemed to him shocking that the parties should be wasting their substance upon a matter in which ten years hence both sides would say it was a matter of perfect indifference whether the case went on or whether it did not.

GLASGOW VETERINARY COLLEGE.

The winter session of the Glasgow Veterinary College was opened on Friday afternoon, Oct. 20, when an address was delivered by Dr. D. N. Knox, president of the Faculty of Physicians and Surgeons of Glasgow. Sir Hugh Shaw Stewart, Bart., presided, and there was a good attendance. Amongst those who accompanied the Chairman to the platform were Principal McCall; Principal Bradley, Royal (Dick) Veterinary College, Edinburgh; Mr. Alan Burns, of Cumbernauld; Mr. Hugh Begg, M.R.C.V.S., Hamilton; Mr. H. R. B. Peile, Greenock; and Mr. Alexander Russell, secretary of the College.

The Chairman said that, while they had with the aid of subscriptions and equivalent grants from the Education Department succeeded in placing the College on a more satisfactory footing, there would undoubtedly be required more money for improvements in the structure. He did not yet quite see where that money was to come from, but he hoped that they would continue to receive the ready support of county councils in the counties of the West of Scotland. (Applause.) Sometimes they heard the man in the street ask what was the use of a veterinary surgeon now that they had taxicabs taking the place of horses in such large numbers. It was sufficient to remind the man in the street that there were such things as health committees connected with burgh and town councils, and that the latter were being moved more and more by the people to take greater care of the food, including milk, which was distributed in the towns and cities. It did not require very great penetration to see that the individual in the future on whom the community would have to depend to a large extent in these matters would be the veterinary surgeon.

Dr. Knox's address took the form of a discourse on the developments of the science of bacteriology, with incidental reference to meat inspection and other subjects, and was listened to with the closest attention.

In moving a vote of thanks to Dr. Knox, Principal Bradley said he did so with pleasure for two special reasons—firstly, because he thought the lecturer deserved their thanks for his most stimulating and suggestive address, and secondly, because the address was delivered by the President of the Faculty of Physicians and Surgeons of Glasgow. He took that meeting as an indication that there was a desire for more co-operation between the medical and the veterinary professions. In the past there could be no question that the two professions had been too far apart. The sooner they came to work together, and very closely together, the better it would be for both of them. (Hear, hear). He was particularly gratified by what Dr. Knox had said about veterinarians and public health questions. There could be no doubt that veterinary surgeons were going to be potent factors in the future in the preservation of the health of the people, and the sooner public bodies and the veterinary profession itself realised that, the better it would be for them all. (App.)

Replying to a vote of thanks for presiding, the Chairman said he was amply rewarded by seeing such a good attendance and listening to such a valuable address. He expressed pleasure at having with them that day the Principal of the Dick Veterinary College, Edinburgh. He (the Chairman) was one of a deputation which went through to Edinburgh to meet an equal number of Dick College representatives to consider the question of the equalisation of fees. He had no doubt the Principal of the Edinburgh College wished them well, as they in Glasgow wished the Edinburgh College well.—*N.B.A.*

Personal.

BENNETT.—To Ralph and Constance Bennett, on October 18th, a son, at "Iona," Hornchurch Road, Romford.

Dick College and Veterinary work of Edinburgh Corporation.

The Cleaning and Lighting Committee of the Edinburgh Town Council had before them on Monday last a deputation from the Royal (Dick) Veterinary College asking that the care of the horses of the Department be put under the College. It seems that at present Principal Dewar, who, as head of the Dick College, looked after this work, has continued it since his resignation, and the College authorities think that this was peculiarly a matter for the College. The deputation consisted of Mr. A. I. Macallum, Principal Bradley, Judge Stevenson, and Mr. R. Anderson, S.S.C., the Secretary of the College. It was agreed to delay a decision for the purpose of certain inquiries being made.—*Edinburgh Evening News.*

ARMY VETERINARY SERVICE.

REGULAR FORCES. ARMY VETERINARY CORPS.

Capt. Edward Brown is placed temporarily on the Half-pay List on account of ill-health. Dated Oct. 25.

OBITUARY.

ROBERT GERALD MELVILLE, M.R.C.V.S., Bridgend, Glam. Graduated, Dublin: July, 1904.

Mr. Melville died on Wednesday, Oct. 18, at the Cottage Hospital, Malton, York, from cerebral hemorrhage, due to an accidental fall. He was only 28, and leaves a widow and a little son.

EDWARD BOGHURST DAWSON, M.R.C.V.S., Tower Lodge, Clacton-on-Sea. Lond: May, 1844.

Death occurred on October 22nd, at the age of 88 years.

MOTOR CARS AND VETERINARY PRACTICE.

Sir,

A motor car has become such a necessary adjunct to a veterinary practice in these days of rapid transit that a short summary of what the annual cost of a small car amounts to would probably interest many of your readers.

Mine is an 8 h.p. Renault two-seater, which, as far as my observations and experience go, is the best and most satisfactory low-powered two-seater on the market to-day.

Petrol	£15 5 0
Oil and grease	2 8 11
Tyres and repairs to tyres	17 3 9
Sundries	1 10 7
Stove and fuel	1 9 0
Repairs to car (broken petrol pipe and bolt)	4 6
Licence of car	3 3 0
Driving licences	10 0
Insurances of man, etc	15 0
Insurance of car, including mechanical breakdown	8 10 0
	£50 19 9

The wages for the man are not included. The estimated mileage for the year is 6750. The cost of the car, I may say, was £205, and the necessary fittings £38, total £243.—Yours faithfully,

HENRY TAYLOR.

Hayward's Heath, October 24.

M.R.C.V.S., qualified 1903, married, requires situation as above in good-class practice. Well up in parturition, good references, 1½ years in present situation. Address, 4104 V.R., 20 Fulham Rd., London, S.W.

For Sale

FREEHOLD house and veterinary practice in a London suburb: no forge; owner retiring. Price £1000, cash down, no offers; only those with capital at command need apply. Introduction given. Address, 4101 V.R., 20 Fulham Road, London, S.W.

For Disposal

ESTABLISHED practice in manufacturing town, Midlands: horse and canine: good house and kennels, working expenses small. Moderate capital required: introduction would be given. Could be greatly increased. Address, 1108 V.R., 20 Fulham Road, London, S.W.

For Sale

PRACTICE in best breeding district in Cumberland. Been in family nearly fifty years. No opposition. Good introduction given. Suitable house: full particulars on application. Address, 1101 V.R., 20 Fulham Road, London, S.W.

Wanted

QUALIFIED assistant required for West-end of London practice. Stage age, salary expected, live out: and where last employed. Address, 1116 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

Change of Address

W. T. BROOKES, M.R.C.V.S.,
Veterinary Infirmary and Shoeing Forge,
The Butts, Warwick.
Late 20 Jury Street, Warwick.

Locum Tenens

L. A. F. DAWSON, M.R.C.V.S.,
Address:
The Cottage, Belton,
Uppingham.
Telephone: No. 2, Belton.

Partnership

THOROUGHLY reliable, practical V.S., age 33, desires partnership, view to succession, or would buy practice or nucleus in a good hunting country. Address, 3109 V.R., 20 Fulham Road, London, S.W.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34. single. Excellent references, interview. Address, 5074 V.R. 20 Fulham Road, London, S.W.

AGENTS REQUIRED in unrepresented districts for the **IMPERIAL ACCIDENT INSURANCE CO., LD.** Est., 1878. Horses Insured against Death from Accident or Disease, Mares for Foaling and Loss of Foals; Farmers' Liability for Accidents to Labourers, Servants, and Workmen's Compensation. Claims paid, £500,000. Address Agency Manager, 17, Pall Mall East, London, S.W.

For Immediate Disposal

YORKS, North Riding. Wanted, reasonable offer. Receipts over £300, good house to go with practice. Rent £12. Good agricultural and breeding district. Present owner 27 years; no opposition; C.C. appointment: introduction given. Address, 5092 V.R., 20 Fulham Road, London, S.W.

Missing Numbers

OWING to claims for missing numbers reaching us often many weeks after date of issue, we have to notify that claims for non-delivery will not be accepted if the date of origin is later than four weeks from date of due delivery in the case of foreign subscribers, or more than fourteen days after printed date in the case of inland subscribers.

H. & W. BROWN.

The Journal of The Board of Agricultuer

ISSUED on the 15th of each month. Twelve months 4/-, three months 1/-, or single copies 4d., direct from the Board of Agriculture and Fisheries, 4 Whitehall Place, London, S.W., or through any bookseller.

Victoria Veterinary Benevolent Fund

President:

W. F. BARRETT, Esq., Fountain Court, Temple, E.C.

FUNDS are urgently needed to enable the Society to extend its relief to distressed Members of the Profession, or to widows and orphans of deceased veterinary surgeons. Annual subscriptions, or donations will be gratefully acknowledged by the Hon. Sec. and Treas.

W. SHIPLEY, Southtown, Great Yarmouth.

For Disposal

WARWICK, freehold house (or lease) 20 Jury Street. Veterinary surgeon's business carried on upon premises for over 60 years, in main street, country town, good hunting district. 3 reception, 6 bedrooms, bath, large yard in rear. 5 loose boxes, stall, large shoeing forge, saddle room, loft, surgery. Ledbrook, Solicitor, Warwick.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

THE FARRIERS' JOURNAL.

A Monthly Magazine for Horse Shoers.
The only paper devoted to the interest of the Shocing Smith.

Price 2d., by post 2½d.

London Office: 6 Malden Lane,
Strand, W.C.

Published by G. WILD, 62 Mount Street,
Ashton-under-Lyne,

CHEAP BOTTLES.

A large quantity of named medical bottles (these have various chemists' names on and washed ready for use)

2oz., 3oz., 4oz., 6oz. and 8oz. at 5/6 a gross.

10oz., 12oz., and 16oz. at 7/- a gross.

Cash with order. Carriage paid on £3 orders within 70 miles, and on £5 orders any distance.

Other bottles and jars quoted for.

F. NEEDHAM,
Beaconsfield Road, Acton Lane,
Chiswick, London, W.

**Non-Poisonous,
Non-Corrosive,
Soluble in Cold Water.**

CHINOSOL

**Active Antiseptic,
Strong Deodorant,
Powerful Germicide.**

Practical experience for years past proves that Chinosol in solution or ointment readily penetrates diseased tissue, thoroughly cleanses and keeps healthy all kinds of wounds, favours granulation and speedy healing, mostly without a scar, and promotes the growth of hair. Chinosol is supplied in

POWDER.

CHINOSOL PURE POWDER for therapeutical preparations used *INTERNALLY*.

CHINOSOL VETERINARY POWDER for lotions, ointments, etc., for *EXTERNAL* use.

CHINOSOL CRUDE GRANULAR FORM } for prompt production of disinfecting fluids for odourless disinfection.

CHINOSOL CRUDE POWDER F }
CHINOSOL SPRINKLING POWDERS for disinfecting and deodorizing stables, sheds, styes, kennels, fowl-houses, etc.

Also **ANTISEPTIC DRESSINGS, OINTMENTS, SOAPS, PESSARIES, CHINOSOL BORACIC DUSTING POWDER, VETERINARY EQUIPMENT**, etc.

Write for full Price List, also for **POCKET CIRCULAR** for *VETERINARY PRACTICE* giving full particulars of treatment of **MILK FEVER, ABORTION, INFECTIOUS VAGINAL CATARRH** in *COWS*, and a great number of approved formulae.

NOTE.—Buyers of our preparations should in their own interest insist in receiving *ORIGINAL PACKAGES* bearing our trade mark with name and address of the Company and full directions inside, they should reject all packages not answering above description *AS NOT GENUINE* and inform us when such are offered.

Sold by Messrs. **Hewlett & Son, Ltd., London;**
Wyleys, Ltd., Coventry.

Willows, Francis & Co., London;
Woolley & Co. Ltd., Manchester.

And all **WHOLESALE CHEMISTS** dealing in *VETERINARY MEDICINES*.

THE CHINOSOL HYGIENIC CO., 16 ROOD LANE, LONDON, E.C.

(**B. KÜHN & Co., Proprietors**)

Royal Veterinary College, London. (Founded 1791.)

Principal and Dean : Professor SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities, etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.), which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts, and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 7th, and terminate on Friday, November 29th, 1912.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

Royal Veterinary College, Camden Town, N.W.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1217.

NOVEMBER 4, 1911.

VOL. XXIV.

THE REGISTER OF 1912.

The Register R.C.V.S. undergoes its final revision during the last few weeks of the year; all changes of address should therefore be notified to the Registrar during the present month if possible, or at least early next month.

We mention the matter for a two-fold reason—partly as a reminder to those members who have changed their address during the year, and partly in the hope of inducing the larger number who may be able to help the Registrar in tracing missing men to do so. Some practitioners are very careless about notifying their changes of address, but not many disappear so completely as to leave all their professional acquaintance ignorant of their whereabouts; and most of us, from time to time, find ourselves possessed of information which may help the Registrar in tracing them. Any such information is just now of material assistance. It may help to keep a careless colleague out of trouble; it will certainly be doing something to increase the accuracy of the Register, and every member should feel it his duty to assist the Registrar in this direction whenever he can.

MOTOR CARS IN VETERINARY PRACTICE.

Our profession did not welcome the advent of motor cars; but they have now become a necessity in many veterinary practices. Probably more members would be using them now than are doing so, were it not for the fact that there is still a good deal of uncertainty regarding the cost of their upkeep. Motorists are often very hazy upon this point; for the majority are well-to-do men who use motors chiefly as luxuries and pay no great attention to their cost. Not many motorists, again, take the trouble to keep reliable records of their mileage: and these are essential to any accurate estimate of the annual cost. The result is that, even in these days, men who contemplate adopting motor traction for professional purposes often find it difficult to forecast the working cost of the change.

Mr. Henry Taylor last week furnished the profession with a short note upon the annual upkeep of one type of small car. Possibly other veterinary motorists also possess reliable figures, and, if so, a comparison of notes might be valuable. A motor-car can travel so much farther and faster than a horse that there is no question of its utility in a busy practice, especially a country one. But there is still doubt, in the minds of many practitioners, as to how its cost compares with that of horse-flesh: definite information on the question will be of assistance in arriving at a conclusion.

STRANGULATED INTESTINE BY MESENTERIC TUMOUR.

I enclose photo of a curious lipoma.

On Saturday the horse, a black hunter gelding (aged), had a fairly stiff day's cub hunting. After returning home he appeared perfectly well, and nothing was noticed until about five in the evening, when he had a sharp attack of colic. He was given a colic draught and I was called in.

On examination I found that he was sweating profusely; the pulse was very fast and thin, but he did not appear in much pain. I gave a dose of physic. Later in the evening I was again called and found that he was showing signs of pain; pulse about the same. He continued to have sharp short attacks of pain at varied intervals until Monday morning at 7 o'clock, when he died. His appearance gave one the suggestion of an animal with a twisted intestine. The only treatment employed after the physic was a sedative, and enemata.

Post-mortem showed a tumour of fatty nature suspended from the mesentery by a pedicle some eight inches long, and attached some six inches below the right kidney to the muscular wall of the abdomen, leaving a small foramen about two inches

across through which a loop of intestine had become snared. I tried to pull the trapped bowel out, but was unable to do so. On making an incision round the base of the tumour, the intestine was shown lying in a pocket in the form of the letter U. The rough diagram shows how at the point of entry and exit both parts were extremely constricted.

Thinking this might be of interest, I had it photographed and send it to you for *The Record* if you think it is of sufficient interest.

WILLIAM S. MULVEY.

Chelmsford, Oct. 24.

ANEURISM OF THE POSTERIOR AORTA.

Subject.—A thoroughbred brood mare in foal, aged, 16 hands.

The mare was unboxed at Harbour apparently all right, and was moved to stables and ate her feed, and within a quarter of an hour was found dead in the position as depicted by photo. As the animal was dead ere I arrived, and being heavily insured I had a photograph taken of the exact position, and made a post-mortem same day, which revealed that the cause of death was due to "rupture of the posterior aorta," the vessel wall of which was in an atheromatous condition. The animal was not tied up, or cast in loose box, and died without a struggle in the peculiar position. Aneurism not verminous.

HENRY B. EVE, M.R.C.V.S.

Folkestone.

ACORN POISONING.

There is an enormous crop of acorns this year, and many cases of poisoning of cattle after eating them have been reported. So far this autumn I have only had one animal, a yearling heifer, dead from this cause, though I have seen a good many mild cases that only amounted to indigestion and constipation.

It is interesting in this connection to point out that acorn poisoning in cattle appears to be confined to this country. Professor Fröhner, in his text-book of Veterinary Toxicology, states that this poisoning is mostly seen in England, and the only authorities he quotes are English, Pugh and Thorburn, though he observes that Schütz had seen indigestion and constipation in cattle after feeding on oak leaves and acorns. It certainly does seem curious that in this country many young cattle die every autumn from acorn poisoning, while no fatal cases are recorded by continental authorities.

Of course a possible explanation is that abroad acorns are more carefully gathered to be fed to swine or to adult cattle or sheep, and not left below the trees as they are in this country.

In contrast to this absence of acorn poisoning in Germany, poisoning by equisetum appears to be very common there, while here we seldom get a case recorded. It does occur, however, and I have seen it several times, and always in cows. The patient behaves very much like it might be expected to do after a large dose of alcohol. It is excited, staggers about, falls, and after a time gets drowsy and even semi-comatose. The symptoms are not dissimilar from those of milk fever. The animals mostly recover.

Enfield.

ABSTRACTS FROM FOREIGN JOURNALS.

THE TREATMENT OF MANGE IN HORSES.

Boudeand discusses (*Revue Générale de Méd. Vét.*) the treatment of equine sarcoptic mange. He advises abstention from the use of all prescriptions which contain petroleum, benzine, or oil of turpentine as a base. These agents irritate the skin, and the action they exert is slow. In consequence of the latter property, numerous applications are necessary, and their use thus becomes costly.

Boudeand recommends an old formula as being always serviceable. He says that a single application of it cures the most obstinate forms of mange without irritation or inflammation of the skin. It is made up of powdered cevadilla seeds, 10 parts, sulphur sublim. 6 parts, burnt alum 4 parts, and oil (exact kind not specified) 100 parts. This mixture should be digested with continuous stirring for at least an hour.

The animal is completely rubbed over by means of two applications (one for each half of the body), with an interval of 48 hours between them. Before the second half of the body is treated, the already dressed first half should be washed with soap and water. In old-standing cases of mange, it is also advisable to thoroughly cleanse the skin with soap and water before commencing treatment.—(*Berliner Tier. Woch.*)

(Cevadilla is now little used, in this country at least, and the note is therefore of some interest.—TRANSL.)

A SPECIFIC SEPTICÆMIA OF CALVES.

Gerspach, of Messkirch, in a communication to a veterinary society at Baden, says that a disease of calves produced by capsuled diplococci is not unknown in that district. Most of the animals attacked are in the sucking age, but it seems immaterial whether they have been fed by the mother or from a bucket. The chief symptoms are loss of appetite, abdominal pain, diarrhœa, difficulty of breathing, and convulsions, and the duration of the illness is from half a day to three days.

The post-mortem appearances suggest anthrax or petechial fever, as there is enormous swelling of the spleen, with numerous hæmorrhages. The gastrointestinal canal is often the seat of a violent sanguineous inflammation, and numerous hæmorrhages exist upon the serous membranes, the diaphragm, etc. Lesions of the navel or the joints are not demonstrable.

The diplococci are demonstrated without difficulty in the spleen, the mesenteric glands, the blood, the liver, and the tissue juices. The capsule is brought very well into view by staining with a 2% solution of gentian violet and decolourising with dilute acetic acid.

Infection takes place by ingestion. Great cleanliness, and the application of an efficient muzzle to prevent the eating of straw, are recommended as prophylactic measures.—(*Berliner Tier. Woch.*)

PHOSPHOROUS POISONING IN POULTRY.

A campaign against rats, prompted by the danger of bubonic plague, has of late been instituted in Hamburg; and phosphorous paste has been largely employed for this purpose. As a result, phosphorous poisonous in poultry, which was previously seldom observed, is now not rare.

Prof. Glage, of Hamburg, summarises his experience of this condition, which he has not yet had the opportunity of observing except in poultry. Poultry seem to have a great appetite for phosphorous as soon as it is accessible to them, for as a rule single birds are not affected. A great number—

not uncommonly nearly the whole stock—are almost always poisoned together. In many of Glage's cases this had led to the suspicion of contagious disease as the cause of death.

Glage adds nothing to the classic descriptions of the symptoms of phosphorous poisoning during life. He remarks, however, upon its rapid course. Often many birds die in a few hours; and in one case a whole stock of eleven fowls died within twenty-four hours.

The post-mortem appearances are very characteristic. The ingesta, especially the contents of the crop and gizzard, possess a strong smell of phosphorous, such as used to accompany the kindling of the phosphorous lucifer matches which were formerly used. Not uncommonly, when the crop is opened, white fumes are seen arising from its contents. The organs, also, and even the blood of the heart, give off the characteristic odour of phosphorous, though not to so high a degree as the contents of the crop and gizzard. Luminosity of the ingesta, in Glage's experience, is less frequently observed. Of the organic lesions, apart from local inflammatory changes of the alimentary mucous membrane, a very well-marked fatty degeneration of the parenchymatous organs is always the most prominent.

The proportion of phosphorous in rat poison is naturally large, and the fowls poisoned by it certainly received much more than the lethal dose. The whole body, especially the contents of the crop, was so charged with phosphorous that in every one of Glage's cases the lesions were very marked. When the history, the lesions, and the characteristic smell of phosphorous alike indicate this as the cause of death, Glage considers chemical examination superfluous; but nevertheless he has always undertaken it to render his diagnosis incontestable. For this purpose he recommends the method of Scheerer, which is based upon the reducibility of silver salts by phosphorous and phosphoric acids.—(*Berliner Tier. Woch.*)

SPIROCHÆTÆ IN THE GASTRIC MUCOUS MEMBRANE OF THE DOG.

Regaud has already discovered and reported the common presence of spirochætæ analogous to those of syphilis in the normal gastric mucous membrane of the dog and cat. Ball and Roquet now report (*Journal de Méd. Vét.*) the result of examinations of the stomachs and intestines of dogs which they have made with a view of determining whether any relation exists between these parasites and the hæmorrhagic gastro-enteric affections of the dog.

These authors propose to call the parasite in question *Spirochæte Regaudi*, after its discoverer. They consider, however, that these spirochætæ have no relation with hæmorrhagic gastro-enteritis, and in this opinion they are supported by Lucet. The spirochætæ are commonly found in the mucous membrane, and are as frequent in normal stomachs as in those showing inflammatory and hæmorrhagic lesions.

The organisms are observed in two forms—long forms showing seven to twelve spirals, and short

ones showing two to six spirals. Preparations obtained by scraping the mucous membrane may be quickly and easily stained by the following procedure. (1) Make a saturated solution of methyl violet 5 B in absolute alcohol. (2) Place from ten to twenty drops of this saturated solution in 10 c.c. of distilled water, and then filter. (3) Stain the preparations, previously fixed by heat or by a mixture of equal parts of absolute alcohol and ether, for from five to ten minutes.

By this method the spirochætæ are stained a dark violet. A 1/6 inch objective may be employed for their examination; but an immersion lens is preferable.—(*Annales de Méd. Vét.*)

W. R. C.

LINCOLNSHIRE VETERINARY MEDICAL ASSOCIATION

The largest attendance secured at a meeting of the Association for some years foregathered at the Albion Hotel, Lincoln, on Friday, Oct. 20th, under the presidency of Mr. W. Grasby, of Daventry, the chief attraction being a demonstration and address by Prof. F. Hobday, upon Dr. Williams' operation for roaring in horses. Supporting the President were Messrs. T. Holmes, Bourne; and G. B. Dickinson, Boston, Vice-Presidents; F. L. Gooch, Stamford; C. Hartley, and C. Hartley, junr., Lincoln; T. Hicks and A. D. Lalor, Sleaford; G. Lockwood, J. Mackinder, Peterborough; J. H. Poles, Whittlesey; T. A. Rudkin, Grantham; T. B. Bindloss, Long Sutton; T. J. Keall, Gainsborough; the visitors including Messrs. L. A. Leach, junr., F. B. Gresham, R. C. Matthews, A. R. Roulledge, Louth.

The Hon. Sec. (Mr. C. W. Townsend) was prevented from being present owing to having met with a serious accident a few days before, and the meeting was unanimous in an expression of sympathy with him at its occurrence and hoped for a speedy recovery.

The minutes as published in *The Veterinary Record* were taken as read.

THE KIRK APPEAL FUND.

The President read a letter from Mr. H. A. Woodruff, pressing the case of Mr. Wm. Kirk in the appeal raised by the London County Council to compel veterinary surgeons to pay for the use of the College crest.

Mr. J. MACKINDER said he had written the Inland Revenue on the matter and they said there was no liability.

Mr. GOOCH said he hoped that would be made public, as a veterinary surgeon had been fined for using the crest.

On the proposition of Mr. Holmes, seconded by Mr. Lalor, it was decided that subscriptions should be left to the inclinations of the members.

THE PROPOSED AMALGAMATION.

Two letters were read from Mr. A. Gofton, the Hon. Sec. of the Royal (Dick) Veterinary College, Edinburgh, with regard to the proposed amalgamation of Veterinary Societies.

The President said the Lincolnshire Society had already expressed its approval of becoming affiliated to the National Association in accordance with the new rules, and on the motion of Mr. Gooch, seconded by Mr. Holmes, this was confirmed, the Secretary to inform Mr. Gofton of the fact.

NEW MEMBERS.

Mr. HENRY LEACH, Boston, was elected a member of the Association, on proposition of Mr. C. Hartley seconded by the President.

Messrs. F. W. MEDLOCK, Peterborough, and A. C. COMERFORD, Caxton, Cambs., proposed at the Peterborough meeting in June, were duly balloted for and elected members.

Mr. R. C. MATTHEWS, Metheringham, was nominated as a member by Mr. Holmes, seconded by Mr. Lalor.

THE VALUE OF THE VENTICLE STRIPPING OPERATION FOR ROARING IN HORSES.

By Prof. FREDK. HOBDAY, F.R.C.V.S., F.R.S.E.

Gentlemen,—My address to you to-day will be a very short one. You have in the last two years heard much about it; yet in reality the real interest in the operation I bring before you lies all in front, and in fact the operation is only in its trial stage. It is the ventricle stripping operation for the relief of roaring. Within the last two hunting seasons—now entering the third—I have operated upon more than 480 patients. About March I shall be able to give to the profession some statistics which may be of value, if only they show that a reasonable proportion of useless animals have been made useful, and then I shall maintain that the operation is justifiable, and if, in addition to satisfying the owners, one can also satisfy the members of the profession then the results will be doubly justified.

Up to the present the results which have been published are sufficiently good to make one assert very emphatically that the operation has come to stay, and to take its proper place as one of those which the modern veterinarian may recommend to his client, affording, as it does, a reasonable prospect of alleviating a very distressful condition, even if not effecting a complete cure.

The actual technique of the operation has already been described before various societies, and in the journals; on the first occasion by Williams, in the paper he read before the American Veterinary Association in 1906, and although there have been some few modifications, especially in the avoidance of injury to the cartilage, the principles are still the same. I must lay claim to a few originalities in these modifications, and I find upon recently discussing the operation with Dr. Williams that Dr. Cary and certain operators on the other side of the Atlantic were working at the same idea at about, if not at, the same time. I refer principally to the idea of operating only through the crico-thyroid ligament without injuring either the thyroid or cricoid cartilage, and to the stripping of both ventricles.

In reference to the latter I have altogether operated now upon over 480 individual horses, more than 200 of which have systematically had the double stripping operation done at the one and the same time, but unluckily such a large proportion of them will not be tested until the next season's hunting commences that I cannot in the present paper give you statistics as to the actual results. I will, however, promise that you shall have them presently.

I am undecided for the moment as to whether it is wiser to strip both at the one time, or to do the left or the paralysed side first, see the result, and then, if necessary, operate on the other some months later. I have about 20 horses now upon which this plan has been adopted, and certainly in some of them the results have been marvellous. They were all hunters and bad roarsers, and the stripping of the left side alleviated the distress, although they still make considerable noise, whilst the second operation some months later has caused still further amelioration, and in at least two cases has enabled the animals to pass veterinary examinations for soundness in wind without comment. It is a plan I have adopted recently in several instances where the horses were of great monetary value, and the time was of no particular object provided the risk was lessened. Everybody, owner and groom alike, dislike the idea of the permanent use of the tracheotomy tube,

partly because of the constant trouble of cleansing, and partly on account of granulations and subsequent stenosis which so often follow as a sequel, and numbers of owners have volunteered the statement that if this operation only saves the animal so that it can work without distress, even if still making a noise, they will have it done. Others have gone so far as to say that even if it only gives them one more hunting season, and the tube has to be inserted eventually they will be grateful.

The operations, however, promise more than this, and I don't think I am exaggerating one bit when I say that it will restore to usefulness quite 90 per cent. of carriage or draught horses, and 75 per cent. of hunters, and that a decent proportion of these shall in addition pass the average veterinary surgeon's examination for soundness in wind. I believe, too, the effect is generally lasting and permanent, as there are now a number under observation in England which have been done about two years, and whose owners assert that they are still satisfactory as to wind.

It has been of particular interest to note the complete adhesion of the ventricle in the cases in which I opened the larynx a second time. Certainly there were some in which the result appeared to be all I could have desired with the left side, and yet the horses made considerable noise until the right ventricle had been treated in the same way. But in others there had not been complete closure, and at the top end there was enough orifice to admit the end of the middle or fore finger.

In regard to early interference I have hesitated to advise owners to have an animal done which was only a slight whistler, but several have had them done on their own initiative, and I must say that the results have certainly been excellent, and several horses have been reported afterwards, when tested, to be sound in wind. I have at the end of the hunting season done a fair number which were only reported as whistlers, but my statistics on the point cannot be complete until more time has elapsed.

I say this advisedly because if chondritis proves at all a sequel to be dreaded even by the most careful operator, then I maintain that it will be better to advise an owner with a whistler, which is not distressed and does not cause great annoyance, to work that horse another season, or until he really is a roarer. If on the other hand, a great proportion of these whistlers become sound horses in so far as their wind is concerned, and the result is permanent, I shall certainly advise in the future that the operation is done in the early stages of the disease.

I mention the fear of the chondritis afterwards because it is a very serious factor to consider, and I know, too, that it was the great bugbear to Möller, Cadiot, Flannery, Fred. Smith, Axe, Raymond, and others who performed arytenoidectomy, but until the end of May this year (over 18 months since the first operation was demonstrated in England) I had never met with a single case, or even suspicions of it. In the month of May last I saw three cases, and one other was reported to me, in all of which the larynx had become distinctly enlarged and very hard, in fact ossified, as a sequel to the operation. In three of these I verified the fact by cutting down to the larynx and exposing it. None of the horses have yet died, so that I have no larynx to show you. I decided not to open it nor to look inside, as I was afraid I might not get the wound to heal again, and two of the horses were useful enough and could gallop without distress, although making considerable noise. Two of these had had the left ventricle alone stripped, and the other two had been through the bilateral operation. The other two had begun to develop symptoms of dyspnoea when galloped, and before being hunted again would certainly have to be tubed.

I mentioned above that I did not re-open the ossified

larynx, as I feared it might not heal readily, and my reason for this was that I knew that sometimes a troublesome sinus formed which was very difficult to close, in fact one such instance had occurred amongst my own cases.

I have thought from observations made that to assist in avoiding both the above complications, the patients should not afterwards be turned out to grass, but be manged fed, partly because of the dependent position of the head during grazing, and partly because of the continuous movement of the muscle of the larynx and throat for so long a period of the day as is necessitated by a horse turned out to pasture. Until the parts of the injured larynx be completely cicatrized I think it to be very essential that this organ and its surrounding muscles and other structures should be allowed as much rest as possible.

Of the bad sequelae likely to follow as the result of the operation, in addition to the fear of chondritis and a troublesome sinus, as mentioned above, my own experience has brought me in contact with deaths from asphyxia and from septicæmia, and of each I have had two instances. Until case No. 206, I never had the slightest anxiety or trouble, but this one broke the record by dying of septicæmia. It was a troop horse in a cavalry regiment, and the veterinary officer (Capt. Hylton Jolliffe, F.R.C.V.S.) and myself thought that we should get a better and quicker adhesion of the right vocal cord (which moved freely) by performing tracheotomy at the same time. This we did, but my knowledge of physiology was defective or I should have known that the mere fact of respiratory air passing in and out of the tubes of the trachea made no difference whatever to the movement of the vocal cord. A septic infection took place—a condition which might of course have occurred as the sequel to any operation, and the patient died on the fifth day afterwards. The second septicæmia case also died on the 5th day.

The deaths from asphyxia are worth recording, because they will prove a warning to other operators to carefully watch the case during the 48 hours after the operation. Both were horses which had previously worn tracheotomy tubes for some time, and in one case there was extensive stenosis of the trachea. I ought to have left the tubes in until after they had become convalescent from the laryngeal wound, but in the one case I allowed it to heal up before operating, and in the other case I purposely closed it up at the same time that the ventricle mucous membranes were stripped. In each case a very sudden spasm of the larynx appeared to take place, and death occurred in a few minutes from asphyxia before tracheotomy could be performed, or even a laryngeal tube inserted.

Since introducing the double stripping operation as a routine measure, tracheotomy has had to be performed several times owing to threatened asphyxia, and the tube left *in situ* for an average period of three or four days, but this is a comparatively minor matter in a hunter, although annoying in a show animal, and the use of a laryngeal tube is better. I have had one made with flattened sides so that the vocal cords do not become impinged upon more than is necessary, for fear of ulceration or abrasion. All these occurred after double stripping, and usually within 24 hours, but we always keep the patient under close observation for 48 hours, and in two instances no disturbance of respiration occurred until the third day afterwards, although these were not alarming enough to necessitate tracheotomy.

The earliest time at which symptoms of dyspnoea occurred was three hours afterwards, but the majority showed signs of trouble between the 5th and 12th hours. The dyspnoea, œdema and swelling of the vocal cords are due to a sudden spasm or paralysis of those organs, and generally one has at least a couple of hours warning in the shape of disturbed and noisy breathing which

gradually becomes dyspnoeic. Tracheotomy gives instant relief, and the horse in half an hour is usually feeding calmly as if nothing had happened.

It would be impossible in a short paper like this to take note of every side of the question, but I am often asked whether a horse which is known to have been so treated should be passed as sound. That they had been, and that many more will be, I am quite convinced, for I will defy even a veterinary surgeon to detect this scar in fully 80% of the patients six months after the operation, and until three months ago I would certainly have advised a client that a hunter which had been operated upon a period of six months earlier for roaring, and was now noiseless, would be worth more than a horse which had not been done and might go wrong in wind any time. Since seeing the four cases of chondritis and ossification of the larynx which I have alluded to above, I think it is only fair that we shall know more about the percentage of this sequel before offering too decisive an opinion.

Time and careful observation alone can settle the point, as also whether one is justified in operating upon a stallion or brood mare. For my own part I fully admit the hereditary aspect of the question. I also know full well that strangles plays an equally large share in the production of roars and whistlers. Eliminate these two factors, heredity and strangles, and one would almost banish roars off the face of the earth.

In reference to the detection of the fact whether an animal has been operated upon or not, as I have stated, it is often quite impossible to detect any scar, and even if one is present it is often almost indistinguishable from the curl in the hair which is often present in this situation. The only sure method I know is to make an effort to cause the horse to attempt to neigh. With a mare having a foal at foot, remove it and allow her to attempt to approach it; or, if possible, starve the subject for some hours and rattle a stable bucket within ear-shot; the resulting effort to neigh gives a totally different sound to that of a healthy horse, for the animal will either be dumb, or neigh with a peculiar muffled effect.

No operation cures every case upon which it is tried, and the operation for roaring is no exception to the rule, but the *technique* advised by our American colleague, Dr. Williams, has been so encouraging that we cannot but feel that we are at last upon the right trail, and that owners and veterinarians alike, not to mention the equine world itself, owe him a debt of gratitude for his dogged perseverance in the face of much discouragement and many difficulties. Let us all do our best to help him to work the matter to a finality, and let us make this an absolute, and so far as possible, a universal and uniform success.

During the delivery of his paper, Prof. Hobday, who had previously given a demonstration of the operation at Messrs. Hartley's yard at Friar Lane, read the following letter:

41, High Street, Dorking.
October 16th, 1911.

Dear Hobday,—I thought you would like to know how the chestnut horse is that you operated on for roaring before the S.C.V.S. He has been turned out about six months. I have had him in from grass about a fortnight and have driven him, but the ground has been too hard to give him what I call a distressing gallop. I have trotted him fast up some of our worst hills here, and all I can hear is a slight roughness. This young horse was a confirmed roarer, but I anticipate from the trial I have given at present that he will be a complete success.—Yours faithfully,

C. W. HOWARD.

Prof. HOBDAY was loudly cheered at the conclusion of his paper, and on the motion of Mr. C. Hartley, seconded by Mr. Rudkin, he was unanimously elected an Associate of the Lincolnshire Society, Mr. Hartley remarking that that was the highest honour they could confer upon him.

The PRESIDENT, in conveying the thanks of the members to Prof. Hobday, said that gentleman had probably had more experience in operating on horses than any other man, and they had been delighted with his operation to-day.

Mr. GOOCH seconded the vote of thanks, and said he had been pleased to be a witness of Prof. Hobday's skill as a surgeon that day. He did not think any man could have given such an anatomical display unless he were a good anatomist. Every detail had been carried out that day in a most minute way, and the paper Prof. Hobday had given them had been most concise and to the point. There was no doubt the operation had come to stay. It would be a relief to owner and animal, and he thought it should be persisted in, and that they should bring it to a finality to help their brethren across the Atlantic. Indeed, he thought the operation should be taught in their schools.

Mr. C. HARTLEY asked to be allowed to add his thanks to Professor Hobday for his masterly exhibition of surgical skill, and for the extremely lucid way in which he had explained the operation. They would keep a daily diary of the effect of the operation and duly report results.

Mr. G. B. DICKINSON said that as a Society they should be very proud in having the opportunity of seeing the operation performed, and they owed their thanks to Professor Hobday for the surgical detail he had gone into. How did they stand, he would like to know, with their clients when they found a horse had been operated on in this manner? Would they be justified in saying such a horse was sound, or were they in duty bound to say the animal had been operated on for some throat affection?

Mr. G. LOCKWOOD said he felt very pleased that he had been privileged to witness the operation under such favourable circumstances and with such a skilled demonstrator, and at the same time their thanks were due to Mr. Hartley for his cordial reception that day. He should like to ask Prof. Hobday if he had any difficulty in administering the anaesthetic in cases where he performed tracheotomy.

Mr. J. MACKINDER said that was not the first operation of the kind he had seen performed, for he remembered it being done by Capt. Smith at Newcastle, and by Prof. Axe. He should be glad to hear of the results in this case, and he hoped the operation would be effective. He was getting older, but he hoped to live to see younger men with more nerve performing the operation.

Mr. RUDKIN also congratulated Prof. Hobday on his operation, adding that he wished they all had his operating skill.

Mr. HARTLEY said some people did not speak favourably of the operation, but he felt convinced it should be persisted in.

Prof. HOBDAY remarked that the fact that owners were satisfied with the results of the operation was a great point in its favour.

Mr. RUDKIN asked how they would stand in a Court of Law with regard to an animal which had undergone such an operation? Could they pass an animal as sound that made any noise whatever?

Mr. DICKINSON thought that an important point. If they found any indication of the operation having been performed on an animal were they justified in passing it as sound.

Mr. RUDKIN: If it makes no noise you pass it for wind.

Mr. HARTLEY said if he knew a horse had had an operation and was sound in his wind he should say so, but he could not pass him as sound. He might say there was no evidence of unsoundness, but that he had lost his mucous membrane.

Mr. ROUTLEDGE said he had a similar operation on a six-year-old horse 15 months ago which grunted if a fly got on him. He still made a noise, but he was neither a whistler nor a roarer. He was three miles an hour better in speed. The noise he made was neither inspiratory or expiratory. He certainly made a noise before, but now was a good hunter.

The PRESIDENT said he had been connected with five or six horses which Prof. Hobday had operated upon, and generally the operation had been an unqualified success. He thought that affected horses should be operated on when young. As to giving a certificate after an operation, he thought if they found a horse was subsequently sound in his wind, then no judge could find fault with them. They owed their thanks to Mr. Hartley for use of his yard and to Mr. Lockwood for producing the subjects they had had that day.

Prof. HOBDAY, in reply to Mr. Lockwood's question, said he generally gave the anæsthetic in cotton wool on the tubes. It was not absolutely necessary to give chloroform. If a horse was no better he was no worse after tracheotomy. He had just returned from a trip to America and Canada where the operation was very highly spoken of, and he knew cases where the value of the horse treated had been increased. As to any legal point which might arise he thought that where a horse had been operated upon the owner or purchaser should be apprised of the fact. He had known four cases where ossification of the larynx had set in, but he

did not think it would after six months. If he came across a good horse that had been operated upon he should tell the prospective owner and advise him to buy him.

Mr. HARTLEY: But you must give documentary evidence.

Prof. HOBDAY: Then you may say he is sound.

Mr. HARTLEY: But is he a sound and perfect animal?

Prof. HOBDAY: Is any animal a sound and perfect animal.

Mr. HARTLEY: But can we say so?

Prof. HOBDAY: Take a horse with a splint. You make him sound.

On the proposition of Mr. Dickinson, seconded by Mr. Hartley, Prof. Hobday was heartily thanked.

Mr. J. MACKINDER proposed a cordial vote of thanks to Mr. Hartley for the accommodation he had given the Society, which was carried with acclamation; Mr. Hartley saying they were perfectly welcome to any service he could render.

The meeting closed with a vote of thanks to the President, who expressed his pleasure at the great success of the meeting, and the company adjourned for tea.

C. W. TOWNSEND, Hon. Sec.

Deaths from Acorn Poisoning

At one farm near Market Drayton five animals have succumbed, four at another, and three at a third, while several single cases are reported. The acorns are unusually plentiful this year, and, grass is scarce. Only a few affected beasts recover. M.T.J.

Changes at the Board of Agriculture.

Earl Carrington has retired from the presidency of the Board of Agriculture, and takes up the office of Lord Privy Seal, while Sir Edward Strachey, the Parliamentary Secretary of the Board, is elevated to the peerage. The new President of the Board is the Right Hon. Walter Runciman, formerly President of the Board of Education, and the new Parliamentary Secretary is Lord Lucas, who has occupied the positions of Under-Secretary of the War Department and Under-Secretary for the Colonies.

There is no doubt that in Earl Carrington and Sir Edward Strachey agriculture possessed two influential representatives on whom much work has fallen as the result of recent developments. Both are practically acquainted with the industry which they represented, and on the most important subjects it was safe in their hands. They may have differed in some of their views, but were agreed on leading questions. They were agreed as to the importance of live stock, and it is certain that their power and influence were used to prevent unnecessary dangers of disease from imports. One reads that Lord Carrington incurred opposition in some quarters because he would not force on the scheme for extending small holdings beyond what in his opinion was safe. To practical agriculturists the idea rather is that, proceeding in the light of his personal and exceptional experience, he placed more reliance on the extension of the small-holdings system than is justified under the conditions existing in the country. Apart from this, Lord Carrington is one of the most enlightened and experienced landowners in the country, and his views on any agricultural subject must always command respect. Sir E. Strachey has always held sound views on most agricultural matters. He is personally well acquainted with the subject, and is in close touch with the agriculturists of the West of England. On dairying matters especially his opinions are always reliable, and in fact one can generally recognise in his utterances a well-informed judgment. Both these public men have rendered good service to agriculture, and their influence will doubtless continue to be exercised in favour of its claims.

It will be so far an advantage, however, to again have the President of the Board in the House of Commons. Mr. Runciman, the new President, is little known in connection with agriculture, but he is a brilliant member of his party, and it is quite probable that his work at the Board of Education may stand him in good stead in the new office, as one of the aims of the future is evidently to be to systematise agricultural education. Lord Lucas, the Parliamentary Secretary of the Board, has had experience at the War Office and at the Colonial Office. He is also an agriculturist and a successful exhibitor of live stock.

It is to be hoped that the new appointments do not indicate any great change of policy, but rather a careful and vigorous carrying out of the methods that have been pursued since the Board was instituted. In recent years, especially in connection with the Development Fund, the duties of the Board have been increased, but there has been so far nothing very revolutionary in its action, unless in the efforts to stimulate the small-holdings movement, as to the ultimate success of which there is considerable scepticism among those who know most about the practical business of agriculture. It will therefore be well to hasten slowly in the direction of the artificial creation of a class of occupiers who are not very well qualified to grapple with difficulties of adverse seasons and low prices. The existing laws against the importation of live stock diseases should be maintained and strengthened. What may be done in connection with the promotion of live stock breeding

remains to be seen, but so far the lines that have already been laid down have been followed, and it is not likely that rash experiments will be tried. The work of the Royal Commission on Horse Breeding has been continued and expanded, but it is to soon to reckon up the results. The plan adopted in Ireland will probably be followed when a stimulus is extended to the improvement of other varieties of stock.

When the Board was instituted the chief aim of those agriculturists who supported the proposal and rendered it possible was to have in the House of Commons a Minister directly representative of the industry and responsible for his Department. Prior to that time the official representative was the Lord President of the Council, whose chief duty related to education. Sometimes an agriculturist of eminence was President, notably the late Duke of Richmond and the late Earl Spencer, and in these circumstances agriculture was efficiently looked after. But when the position was filled by a politician not in any way connected with the industry, and having little sympathy with it, the chances of adequate consideration were remote. It was to get rid of this uncertainty that the establishment of the Board was supported.

Under the old régime two branches had been developed in a highly satisfactory manner—the one dealing with diseases of animals, and the other with the collection and publication of statistics, and under the Board both have rendered excellent service. The Statistical Department has become one of the best in any country. No less will be said for the Veterinary Department.

Ministers may come and go, but the officers who under able direction carry out the important duties just referred to are those who give most assistance to farmers in the daily conduct of their business, though no doubt they are much helped and encouraged by the support and intelligent appreciation of the official heads of the Board.—*Live Stock Journal*.

GLASGOW VETERINARY COLLEGE (INCORPORATED.)

ADVANCE IN VETERINARY AND MEDICAL SCIENCE.—Address delivered at the opening of Session by Dr. DAVID N. KNOX, President of the Royal Faculty of Physicians and Surgeons of Glasgow.

It gives me the very greatest pleasure to come here and give the introductory lecture to the students now beginning a new session at the Veterinary College, and that for two reasons. In the first place, as President of the Royal Faculty of Physicians and Surgeons, I wish to show the great interest which the Faculty entertains towards this College and the work of the veterinary profession, and, second, because about thirty years ago I was one of the professors of this college, and did what I then could to help your distinguished Principal to impart the necessary instruction to candidates for the M.R.C.V.S. It now gives me, after this long interval, very great pleasure to return even if but for an hour to this lecture room to congratulate Principal McCall and you, the students, on the new era that has opened for the College, the greater facilities for instruction that have now been provided, and the new additions to the curriculum that have been made since my time.

MEDICINE AND SURGERY INDIVISIBLE.

All medical men who have ever been engaged in teaching or research—that is, all who have ever done more than merely try to make a living by their profession—know that the great science of medicine and surgery is one and indivisible, and that there is no gulf between human and veterinary medicine. There are specialities, demanding special technical instruction and

experience for their highest fulfilment in practice, but they are based on scientific principles and investigations, scientific methods of study and of treatment common to both. Further, each department of study on the human or veterinary side sheds the greatest light on the similar department of the other. As a former teacher of human anatomy I often found that some obscure structure in the human body was brilliantly illuminated when the details of the same structure in the domestic animals were fully investigated. In embryology especially was this the case, many of the details of foetal life and structure being only possible of thorough examination and understanding when studied in animals. In all departments of veterinary medicine and pathology the same principle holds good. The veterinarian is constantly deriving benefit from the work of the human pathologist, as well as conferring benefits in return on his medical brethren. It is thus quite impossible to separate the two branches of study or to distinguish between the education of the two sets of practitioners. The veterinary surgeon must be as highly trained as the medical in all subjects common to him and the ordinary medical practitioner, while in the more purely special subjects of the veterinary surgeon he ought to be even more highly trained than the medical, if that be possible. This is an idea of mine formerly expressed, I think, in this very room, and I have seen no reason to change it. It is based on the fact that the veterinary surgeon gets no great assistance in diagnosis or even as to the results of treatment from his patients. They cannot tell him where they feel pain, or when their illness began, or what part of the body is affected. This must be found out unaided by the practitioner, guided by his scientific knowledge of anatomy, physiology, and pathology. It is thus obvious that to be successful in his work the veterinary practitioner must have a thorough scientific knowledge of his profession always at his finger-tips. The student must therefore seek while in the dissecting-room or hospital to imprint an accurate and lasting picture of what he sees in his mind. He must be able to put his finger on any part of his patient's body and tell what structures lie below, what are the normal functions of the tissues or organ, and when the slightest abnormality is detected, recognise the changes taking place with their local and general significance. To do this successfully requires high scientific attainments, supported and emphasised by large and wide experience. The same knowledge is required of the medical man, but his patients can often give him the greatest possible assistance by what they tell him and by the facility with which they can be examined. I think, therefore, you will see what a grand and noble profession the veterinary one is when practised as it should be, and what a great responsibility lies on all students so to spend not merely their days here at college, but their whole life in the endeavour to attain to this high standard.

NO BACTERIOLOGY THIRTY YEARS AGO.

In looking over the Calendar of the College I notice that there is a class now taught that was not taught in my time, viz., Bacteriology. Thirty years ago there was no science of bacteriology, in fact the whole subject was unknown. It is true that certain scattered observations had been made by different people at different times, but they were few and far between, and nobody had the slightest notion that they were or could be co-related. Lady Mary Wortley Montague, in her letters from Turkey, had told us more than a hundred years ago of the alleged value of inoculation of the poison of small-pox in reducing the dreadful severity of that then very common disease. But when inoculation was tried in this country it was found to be not only almost valueless but most dangerous, and had to be given up. Then Edward Jenner discovered the virtues of vaccination,

and this is still practised, with the best results. No one till quite recently thought these two discoveries had any close relation to each other, still less that the failure of the one and the success of the other could be explained scientifically and as part of a general principle. The next observation of value in point of time was Pasteur's great discovery and demonstration of the nature of fermentation. It seems a great puzzle for anybody to believe that this process of fermentation had any relation to the processes of inoculation and vaccination—if it stood alone. But these three processes were the first shafts of light that heralded the dawn of the new science of bacteriology.

LISTER'S DISCOVERIES.

Lord Lister, then a surgeon in our Glasgow Royal Infirmary, was the first who had the penetration to perceive that more lay behind Pasteur's discovery than even Pasteur himself had dreamt of. Pasteur was a chemist, and had attacked the problem of fermentation from the chemical side, though he soon discovered that the process was biological and not chemical. Lister was a great physiologist, and had, therefore, a wider outlook on biology than Pasteur had. He soon, by the aid of the microscope, was able to prove that the putrefaction of pus, so common in his practice then, was a similar or even identical process with Pasteur's fermentation. He then proceeded to reason out the process: he found that germs, or at least living particles, entered open wounds from the air and multiplied in the discharges, producing not merely a foul smell, but also producing a material that was absorbed into the blood vessels which set up fever, secondary abscesses, or foci of inflammation, and then death by poisoning of the nerve centres. Lister's knowledge, at least as expounded to us students by himself, was still very meagre. He still believed in "laudable" pus as a healthy excretion from certain tissues, and his first efforts in treatment were to prevent this pus from becoming putrid by the intrusion of germs or organic particles from the air. He frequently demonstrated these germs as movable vibratory bodies easily seen under a low power of the microscope. He then went a step further and excluded the "motes of the sunbeam" from any wound freshly made, and in many cases found that pus did not form at all, while in other cases it did form. These successes and apparent failures made him investigate the whole process of inflammation and suppuration anew, with most important results. This investigation was a long and complicated process—in fact at first a mere groping in the dark. His first endeavour was to secure healing of wounds by what some of you know is called first intention, that is, without any symptom of inflammation or the formation of matter, and after many experiments he proved that if the dust-laden air could be excluded from or filtered before it entered a freshly made wound no sign of inflammation or suppuration would be set up, and that the wound would heal most kindly and quickly even when operations of the greatest severity were performed, or were performed on tissues and organs like the peritoneum or the brain, which up till then it had been absolutely fatal to touch with a knife. He proved that the skin of the patient and the atmosphere around were full of germs, called in a general way bacteria, and that if these could be killed or removed thoroughly the surgeon could almost do what he liked in the way of successful operations. This was the theory of what he called antiseptic surgery.

Lister soon found, however, that his system was not perfect in practice, however perfect it seemed in theory. His methods were far from being sufficient in spite of the ingenuity and skill exercised in devising them. A great deal of the success of the operations seemed to depend on the health and varying powers of resistance of the tissues, as well as on the atmosphere and even the kind

of building in which an operation was performed. Further, it was found that in suppuration occurring without any apparent external wound, the pus contained in such abscesses, while it might not contain any of the germs of putrefaction, contained other germs of different types, and which could only be found by the use of very high powers of the microscope. Such germs were speedily shown to have obtained entrance to the body by means of the air passages or other natural channels, and so to have permeated the whole body. Their presence weakened the tissues or found a nidus in some injured spot, especially in a wound, and these developed so rapidly as greatly to interfere with the success of the surgeon's work. To counteract this and other possibilities leading to the entrance of germs to wounds, Lister methods were gradually improved, especially by continental surgeons. The body of the patient, the hands of the surgeon, his instruments and dressings were sterilised. New operating theatres were built which had never been polluted by septic materials, and the new era of Aseptic Surgery was introduced.

Let us again return to putrefaction. On this process being more carefully examined, especially in the light of further investigations, by Pasteur and the experiments of Lister, it was seen that a great variety of germs were concerned in it. Further, that many of these germs were able to live in the bodies of men and animals, and therein to give rise apparently to various forms of disease. Immediately pathologists in all parts of the world set to work to elucidate the life histories of these germs and to classify them according to their more important differences. Such observations were astonishingly rich in results. Certain diseases, called hospital diseases, were at once explained as the result of the intrusion of certain germs into the body. I refer to such diseases as erysipelas, blood-poisoning, diphtheria, tuberculosis, and anthrax both in man and animals. Inflammation was seen to be in the beginning a reaction against the intrusion of such germs, while the death of tissue and suppuration indicated the failure of such reaction and the intoxication of the system or the tissues by the powerful virus produced by these germs. Further, such germs were found to be transmissible from man to man, some from animals to men, and others from men to animals. Such transmission enlightened us as to the meaning of infection and contagion, words that had for long been used vaguely and ignorantly, but now became precise and scientific. By the word scientific I mean that our knowledge is now based on facts and no longer on theories that the discoveries of to-morrow may require us to give up and unlearn. Our knowledge is being added to every day, and is far from being complete in any respect. Every observation and experiment made is immediately repeated by other observers and experimenters and approved or disproved or explained. One great source of information as to the nature and relations of germs comes from the results of cultivation. It was a great discovery when we found out that germs could be taken from the body and cultivated on a suitable soil in a suitable atmosphere and temperature. They could thus be isolated, their growth and development watched, and their effect when in the pure state they were injected into the living and healthy body. Then only it became possible to say definitely that certain diseases were always due to the growth in the body of certain germs; that the intrusion of a given germ, such as tubercle, would always produce some form of tuberculosis, and would produce no other disease; that in the same way the germ of anthrax, if inoculated, would certainly produce anthrax and nothing else. We then know in our medical practice that if a number of people are affected with small-pox that the disease is due in all the cases to the contagion of small-pox and to no other germ, and the medical officer of health at once acts on this knowledge in his efforts to combat the disease.

Another curious result from cultivation was arrived at. One would expect that after cultivation, by getting rid of impurities during the process, that the virulence of the poison *pro tanto* would be increased; and that is so. But if you take some of the first cultivation, put it again in a suitable medium, and cultivate it a second time, in is found that the poison is less virulent than before, and gets less and less virulent with each succeeding cultivation. In some cases these cultivation experiments can be performed in the bodies of animals with like results, the poison becoming less virulent in the second animal than in the first, and still less virulent in the third. This principle has always been employed in the case of vaccine matter. At first each child was vaccinated from another child, but now for obvious reasons it is found to be better to use the calf as the intermediary. The plan of producing a milder virus in this way is called the *attenuation* of the virus, and it is found in practice that a weak virus may be injected into a healthy animal without producing any marked effect. But on experiment it is found that an animal so treated is no longer susceptible to the stronger virus; that is, an animal which might have been killed by a dose of strong virus will suffer but little if, previous to this injection of a strong virus, the animal has been treated by the injection of the attenuated virus. Such an animal is therefore said to be immune or protected by these mild injections. This is a most important principle, and has given rise to many of the processes adopted by surgeons and veterinary surgeons in the diagnosis and treatment of infective or contagious diseases.

TOXINS.

In producing this immunity the fluid filtrate from a culture of the germ is generally used, and is called the toxin. After the injection of a toxin into the body of an animal, and especially after several such injections, it is found that in the blood serum of that animal substances make their appearance which can neutralise the poisonous action of the toxin. These substances are found in the serum, and this serum, so enriched after being separated from the clot, is made use of as an antidote to the toxin, and is called the anti-toxin in popular language. The toxin of a disease may be produced in the body of the animal, producing all the symptoms of the disease, but when the antitoxin is timeously injected the toxin may be neutralised and the symptoms subside. We often see this in diphtheria. In the case of diphtheria the animal used to produce this antitoxic serum in the horse, because a large quantity of serum may be obtained from a horse's blood, quite a number of which are maintained at the Institutes now established for the production of the various serums. A horse in perfect health is taken and is slowly habituated to the action of the toxin, beginning at first with very small doses of a weak toxin, and gradually day by day injecting larger doses of stronger toxins. By careful watching experienced observers know when the blood serum has reached its highest antitoxic value, and then the animal is bled from the jugular vein to the limits of safety. The serum is then separated under most rigid antiseptic precautions, and bottled up. The animal is then allowed a few months to recover, and then the process is repeated again and again. The valuable therapeutic fact is thus learnt that not only is the animal subjected to this process immunised, but if some of the serum is injected into another animal it also will be immunised. This forms the foundation for what is becoming a great department of therapeutics, equally applicable to men and animals, and usually spoken of as Serum Therapy.

IMMUNITY IN ANIMALS OR MAN.

I do not wish you to suppose that in *every case* in which we have isolated and cultivated the disease germ that we have as yet obtained a neutralising serum or

produced immunity in animals or man. The typical process, as given here, is true of diphtheria, typhoid fever, and in a less degree of tetanus—that is, immunity in tetanus may be obtained in animals, but only to a very slight degree in man. There is yet an enormous amount of work to be done to fill up the gaps in our knowledge, but when you think of the multitude of investigators who are engaged on the work, with the almost daily reports of successful experiment, it certainly cannot be long before further results of the utmost practical value to surgeons, physicians, and veterinarians are attained. This is a research that must be especially valuable to members of your profession in the immediate future. At present you are using what are probably the best, if not the only practicable, methods of controlling infective or epidemic diseases, by stamping them out by the very expensive and wasteful slaughter of infected animals. I saw a notice not long ago in the papers of a small epidemic in England being thus stamped out by the slaughter of 62 cattle. No one can call this a scientific method of treating disease. It is merely a makeshift to prevent a much greater loss, but it is after all only a testimony to our ignorance. It only requires steady, persistent investigation on what are now well-known lines, and the secret will be discovered whereby present expedients will be made unnecessary, the public health of the community freed from present dangers, the owner's pocket saved, and the veterinary surgeon reap a splendid pecuniary reward. I hope, therefore, that what I have said will excite your sympathy and stimulate you to join in the work of investigation and experiment. I have laid before you a very few of the points of a most fascinating story. The work done so far is the first volume only, so to speak, of a system of preventive medicine that seems likely before long to completely remodel the work, both of physicians and veterinary surgeons.

MALTA FEVER.

Another point in the life-story of disease germs is the paths by which they obtain entrance to the animal body. First, some obtain entrance through the air passages from the atmosphere. This is the case with that common disease called "influenza," the very name of which embodies the theory of its mode of infection. The same is also true of most of our specific fevers. The tubercle bacillus also in many cases may enter by this path, though owing to its universality it has other channels open to it. As tuberculosis is one of the diseases communicable from animals to man, a large number of cases of this disease in man arise by being carried by milk or other articles of diet into the alimentary canal, and thence spreading throughout the system. In preventing both of these methods of infection lies a great part of the work of veterinary surgeons and medical officers of health. With reference to the infection through milk I would like for a moment to refer to a quite recent discovery. There has been a fever known for at least 2000 years as occurring in Rome, Naples, Malta, and other places on the shores of the Mediterranean, and popularly known as Malta fever. The cause of this could not be discovered, and after much observation and elimination of all known causes it was only in 1887 that suspicion fell on the goats,* of which there are great numbers in the Island of Malta, and whose milk was commonly supplied to the inhabitants by the goat being milked before the door, so as to secure purity and freshness and to prevent any suspicion of contamination. An army medical officer, Col. Bruce, investigated the goats' milk, and proved conclusively that the fever was due to a germ contained in the milk. He further showed that about 50 per cent. of all the goats in the island were affected

with the disease, and were giving off the germs in myriads in their milk. Bruce's observations and experiments have been repeated by many others, and now there is no doubt as to the cause of Malta Fever. Henceforth no tourist landing for a few hours to see the famous island while his ship is coaling need fear to catch a fever that was for centuries supposed to be endemic, and which was practically universal among the permanent residents.

MOSQUITOS.

A still more interesting discovery was that mosquitos, which haunt all tropical marsh lands, lakes, and rivers, were the means of conveying the germs of malarial fever, from one man to another. Malarial fever is, as you know, the great scourge of all tropical climates, and the discovery has not only led to successful efforts being made for its prevention and treatment, but has also opened up further fields of research into the causes of yellow fever, sleeping sickness, and numerous other tropical diseases, both of men and animals. Here let me say that a young friend of my own who was holding an appointment in the Cape Mounted Police, South Africa, and frequently witnessed the work of veterinary surgeons inoculating cattle and horses against infective diseases, became so interested in the work that he threw up his appointment, and came home to study for the veterinary profession. He was a student in this College for one year, and then went to London. He returned after he got his diploma to South Africa with a Government appointment of much value. He has now gone to New Zealand, and is one of the principal veterinary surgeons of that progressive colony, and in Government employ.

A SUGGESTION.

I think I have now said enough on this part of my subject. I have merely adverted to a very few points, and that in the briefest possible way. I have tried, as I said, to engage your attention and excite your imagination over a very wonderful story of a department of medical study which lies at the basis of all true progress in public health. My remarks may furnish another moral, and give a hint, not so much to the students as to the governors of this College and to the veterinary profession, including the students. You know that in the medical profession we have a body of men who have undergone a special training, and have obtained a special diploma of Public Health, and who are the recognised officers of Public Health throughout the country. I would like to suggest that a similar body of veterinary D.P.H. should be instituted by your Royal College of Veterinary Surgeons. I am well aware that there is a Society already in existence called the Association of Veterinary Officers of Public Health—a Society that is doing, and has done, most excellent work in various places. I have no wish to depreciate the members of that Society. They are in the same position, however, that the early Medical Officers of Public Health were in Glasgow forty years ago—the period when the late Sir Wm. T. Gairdner and Dr. J. B. Russell were at the head of health matters, and who began the work that has since been so worthily carried on by their successors. These men were giants, and did giants' work. The ordinary medical practitioner is no more able to carry on their work successfully without special training than he can fly without a special aviation car. Your Association of Veterinary Officers of Public Health has doubtless great men among its members, fitted in every way for their work by their own self-training, but I am sure your profession would be as much benefited by a specially trained class of health officers as ours has been. I had the opportunity of reading a few days ago the proceedings of your Society at its annual conference in Edinburgh, and I was struck by the knowledge of the various Acts relating to byres, cowsheds, and dairies possessed by the

* It was nearly 20 years later that this connection was demonstrated.

speakers, by the accuracy and fullness of their reasoning as regards meat and milk inspection, and the relations of animal diseases such as tubercle to the general health of the community. I also saw, however, that the various speakers felt that for the success of their work something more was wanting. The Chairman suggested that as regards the inspection of meat "he felt confident that in time, as posts fell vacant or as public bodies became educated to the vast difference that existed between the man who had made a study of human diseases and the man who had made a study of animal diseases, especially those communicable to man, then they would see a change in the type of man appointed to supervise meat inspection." Now there is a great deal of truth in all that, but is it the whole truth? Are all veterinary surgeons, however skilled they may be in the diagnosis and treatment of animal diseases, equally skilled meat inspectors? I don't think Mr. Robb would say that they were. There is more wanting than that veterinarians should be appointed meat inspectors. Mr. Lindsay put his finger on the spot when he said, "In order that the district inspectors would be able to confirm their diagnosis in doubtful cases, a laboratory ought to be established by the central authority at some convenient place." This gives the whole difficulty away by admitting that there are doubtful cases where no man, however experienced, can with the naked eye and unaided by more scientific tests, recognise all incipient cases of disease, or should be trusted to pass milk or carcasses as in all cases fit for human food. Scientific laboratories are an absolute necessity of efficient inspection, and my proposal comes to this—that we should have a class of veterinary surgeons especially skilled and capable of working in such laboratories. I am afraid that at present, and for some time to come, the officials in such laboratories would mostly require to be found in the ranks of Medical Officers of Health. In fact, I do not see where else properly trained bacteriologists could be obtained, and until the veterinary profession wake up to the necessity of providing such training for their inspectors this difficulty will exist.

AN ALTERNATIVE.

If the veterinary surgeons here to-day think this too big an order to execute all at once—I mean to institute a veterinary D.P.H.—there is an alternative that might be easier of execution and which I should like to see this college undertake. It is to institute what might be called post-graduate courses in Public Health where veterinary surgeons might come and receive special practical training in public health work to fit them for special posts as inspectors, etc. This would require the setting up of a public health laboratory where specialised instruction in chemistry and bacteriology might be given, and this could be followed by a practical examination on the subjects taught. In every medical school there are such laboratories, and to a large extent they may be made self-supporting. Whether other subjects than these I have mentioned should be included in such a course will form matter for future consideration and arrangement, but the two subjects that I have mentioned seem of paramount importance, and they cannot be learnt from books or Acts of Parliament. I would like to see this college undertake such work, as I have not the slightest doubt it would redound to the credit of the college and increase the numbers of its students. Other colleges would be compelled to follow suit, and then the way would be paved for action by the R.C.V.S., and the granting of a diploma that would mark out its possessors as belonging to a specially high grade of the veterinary profession. I am the more inclined to make this suggestion as there can be no doubt that the number of inspectorships in this country is bound to increase, and the more lucrative posts will

go to the most highly-qualified men, while abroad there is certain to be an enormous demand in the future for veterinary surgeons, and there each man will require to have his own laboratory and be capable of doing all the work himself. What a splendid training for such work would be a six-months' course of laboratory work at a recognised college like this and under competent teachers!

Personal.

The Sanitary Committee of the Reigate Town Council reported that applications for the post of Veterinary Inspector of Cows had been received from:—Messrs. Walter Smithers, Dorking; Arnold Spicer, Oxted; and Chas. A. Squair, Reigate. The Committee recommended that Mr. Charles A. Squair be appointed. Mr. Squair has been veterinary inspector for 17 years.

We understand that there were 17 applicants, and the 3 mentioned in *The Surrey Mirror* was short leet

MOTOR CARS AND VETERINARY PRACTICE.

Sir,

In last week's issue of *The Veterinary Record* Mr. Taylor has been good enough to supply you with a short summary of one year's cost of running an 8 h.p. two-seater "Renault" car over 6750 miles.

This summary is altogether too short, and I would suggest that Mr. Taylor should complete the picture, so that it might be a reliable guide to those veterinary surgeons who contemplate purchasing a car.

As published, the account shows a running cost of less than 2d. per mile, but this will be more than doubled when he adds £50 for depreciation, £10 for interest on purchase price, and £15 for a man to wash up and trim the car.

I presume Mr. Taylor's car was new when bought, and anticipate that, like others, he will have cause in each succeeding year to considerably extend the amount under the item "sundries."—Yours faithfully,

HUGH BEGG.

THE 'RECORD' PRECISION SYRINGE.

**The FINALITY of
Hypodermic and Serum Syringes.**

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Wanted

ASSISTANT for country practice, must be used to rough work and willing to do it. References as to practical knowledge, honesty and sobriety indispensable. Address, 1113 V.R., 20 Fulham Road, London, S.W.

For Disposal

ESTABLISHED practice in manufacturing town, Midlands: horse and canine: good house and kennels, working expenses small. Moderate capital required: introduction would be given. Could be greatly increased. Address, 1108 V.R., 20 Fulham Road, London, S.W.

For Sale

PRACTICE in best breeding district in Cumberland. Been in family nearly fifty years. No opposition. Good introduction given. Suitable house: full particulars on application. Address, 1101 V.R., 20 Fulham Road, London, S.W.

Partnership

THOROUGHLY reliable, practical V.S., age 33, desires partnership, view to succession, or would buy practice or nucleus in a good hunting country. Address, 3109 V.R., 20 Fulham Road, London, S.W.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

LOCUM, assistant, branch manager, veterinary surgeon desires permanency, sporting, hunting, country practice. Experienced, reliable, practical, hard worker, castrate standing, good obstetrician, 34. single. Excellent references, interview. Address, 5074 V.R. 20 Fulham Road, London, S.W.

AGENTS REQUIRED in unrepresented districts for the **IMPERIAL ACCIDENT INSURANCE Co., LD.** Est., 1878. Horses Insured against Death from Accident or Disease, Mares for Foaling and Loss of Foals; Farmers' Liability for Accidents to Labourers, Servants, and Workmen's Compensation. Claims paid, £500,000. Address Agency Manager, 17, Pall Mall East, London, S.W.

Victoria Veterinary Benevolent Fund

President:

W. F. BARRETT, Esq., Fountain Court, Temple, E.C.

FUNDS are urgently needed to enable the Society to extend its relief to distressed Members of the Profession, or to widows and orphans of deceased veterinary surgeons. Annual subscriptions, or donations will be gratefully acknowledged by the Hon. Sec. and Treas.

W. SHIPLEY, Southtown, Great Yarmouth.

For Disposal

WARWICK, freehold house (or lease) 20 Jury Street. Veterinary surgeon's business carried on upon premises for over 50 years, in main street, country town, good hunting district. 3 reception, 6 bedrooms, bath, large yard in rear. 5 loose boxes, stall, large shoeing forge, saddle room, loft, surgery. Ledbrook, Solicitor, Warwick.

Locum Tenens

M.R.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Gregg's Tracheotomy Tube

MADE in one piece (improved hinged flanges.) The best and the cheapest Tube on the Market. Used by all up-to-date Veterinary Surgeons. Satisfaction guaranteed. Price 15/- Robertson & Co., Victoria Square, Belfast.

THE FARRIERS' JOURNAL.

A Monthly Magazine for Horse Shoers.
The only paper devoted to the interest of
the Shocing Smith.

Price 2d., by post 2½d.

London Office: 6 Maiden Lane,
Strand, W.C.

Published by **G. WILD**, 62 Mount Street,
Ashton-under-Lyne.

CHEAP BOTTLES.

A large quantity of named medical bottles (these have various chemists' names on and washed ready for use)
2oz., 3oz., 4oz., 6oz. and 8oz. at 5/6 a gross.
10oz., 12oz., and 16oz. at 7/- a gross.
Cash with order. Carriage paid on £3 orders within 70 miles, and on £5 orders any distance.
Other bottles and jars quoted for.

F. NEEDHAM,
Beaconsfield Road, Acton Lane,
Chiswick, London, W.

"MAGNUM" PESSARIES.

(HEWLETT'S)

"Magnum" Pessaries are prepared with a medicated non-oily base which is both effective as a Uterine Antiseptic and of special benefit in Parturition both in Cows and Mares.

A "Magnum" Pessary should be inserted directly after parturition in order to maintain the Uterus in a healthy state. It can be inserted with the greatest ease and will keep the parts in a thoroughly antiseptic condition for a lengthy period.

Alkaline "Magnum" Pessaries have recently been recommended to neutralise excessive acidity of Vaginal secretion.

"Magnum" Pessaries are supplied according to various formulæ as below, and Veterinary Surgeons' own formulæ can be made up as required.

		Doz.	12 doz. @	Doz.

35-42 CHARLOTTE STREET, LONDON, E.C.

Royal Veterinary College, London.

(Founded 1791.)

Principal and Dean : Professor SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities, etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.), which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts, and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 7th, and terminate on Friday, November 29th, 1912.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

Royal Veterinary College, Camden Town, N.W.

VOL. XXIV.

THE PROPOSED SCOTCH BOARD OF AGRICULTURE.

The Government are contemplating a step which, however well intentioned, cannot fail to be detrimental to British agriculture. It is proposed to establish a separate Board of Agriculture for Scotland which, as one of its most important duties, is to administer the Contagious Diseases of Animals Acts throughout Scotland. It may be fully admitted that, as regards some departments of agricultural industry, there is something to be said in favour of transferring the administration of Scotch affairs to a Scotch authority. But we, as veterinary surgeons, are concerned only with our one very important department of the suppression of animal disease. In this, there is no doubt that the proposed division of authority, should it take place, will be a grave mistake.

Areas of country enclosed within one sea-line should, so far as the control of animal disease is concerned, be under one governing body. That has hitherto been done in Great Britain with good results, and in Ireland with even better. On the Continent, for obvious reasons, it cannot be done, and a great deal of the difficulty in repressing animal disease in Europe is due to the long lines of frontier with different regulations under different Governments on either side, dealing with questions in which, as has just been well said, "Absolute unanimity of treatment guided by one mind is essential for success." The Government's proposal will introduce the same difficulty into Great Britain, and it is with regard to outbreaks of disease occurring near the Border that its effects will be most marked.

In dealing with rapidly spreading epidemics such as foot-and-mouth disease, prompt decision and vigorous action—the latter perhaps extending considerable distances from the centre of the outbreak—are essential. These are possible under our present régime, as the success with which the repeated invasions of foot-and-mouth disease this year have been dealt with testifies. They would be impossible, in the long run, under the proposed new system. Different regulations would be established; differences of opinion regarding the restriction necessary would be certain to arise; and, worst of all, the two Boards might even disagree upon the nature of an outbreak of disease near the Border. In the end Scotch and English Agriculture alike would suffer, perhaps to an incalculable extent.

Agriculturists in both countries are alive to the dangers of the innovation. The Scottish Chamber of Agriculture, by a large majority has protested against it; and similar protests, so far unanimous,

have been sent in by agricultural associations in England.

There is yet time, in all probability, for vigorous concerted action by agriculturists to prevail upon the Government to drop this ill-considered proposal; and veterinary surgeons, so far as lies in their power, should endeavour to assist the agriculturists. Veterinary associations might join in the protest; and veterinary practitioners should certainly endeavour to stimulate the more locally influential of their agricultural clients to organised resistance. And finally, any practitioner having access to a Member of Parliament may now approach him on a subject of infinitely greater import to the profession and the nation than the redress of such minor veterinary grievances as those of motoring dues and jury service.

VETERINARY TRAINING FOR PUBLIC HEALTH WORK.

Dr. Knox's opening address at the Glasgow Veterinary School appeared in our pages last week. This week we reprint two notes upon it—one from *The Lancet*, which is mainly an echo of Dr. Knox's views, and the other a spirited comment by Prof. McCall. We are glad the veteran Principal of the Glasgow Veterinary School has spoken out; for both Dr. Knox's address and *The Lancet's* note illustrated a misconception which is very common amongst medical men.

Most medical men now acknowledge the need for an adequately trained State Veterinary Service. Very few seem to realise how much our profession has done to meet that need. Many, in fact, speak of laboratory instruction for veterinary surgeons, and the higher education of the profession, as if both were undertakings yet to be commenced; whereas both have long been in full vogue amongst us. Dr. Knox, in advising the Glasgow School to initiate post-graduate courses, seemed quite unaware that such courses have been established for years at various centres in England. Possibly Dr. Knox, and certainly many another medical man, would be surprised to hear from Prof. McCall that veterinary students for the diploma receive practical training in bacteriology and meat inspection at every school in the United Kingdom. And yet that state of things dates from the last century!

The ordinary professional veterinary curriculum is fully upon the scientific level of the medical one. The same may be said of the post-graduate instruction of the two professions in sanitary science; only, as the demand for veterinarians in this capacity is as yet not great, a few centres of post-graduate veterinary instruction have so far sufficed to meet it. Doubtless fresh centres will open as the demand increases, but at present, whenever a new appointment in State veterinary medicine becomes available, a specially trained veterinary sanitarian can be found to fill it. Medical men who recognise the position we shall one day fill in the public health services might well also learn to recognise how far we ourselves have already travelled unaided towards it.

INTUSSUSCEPTION.

By Lieut. H. C. STEWART, A.V.C.

Station Veterinary Hospital, Secunderabad.

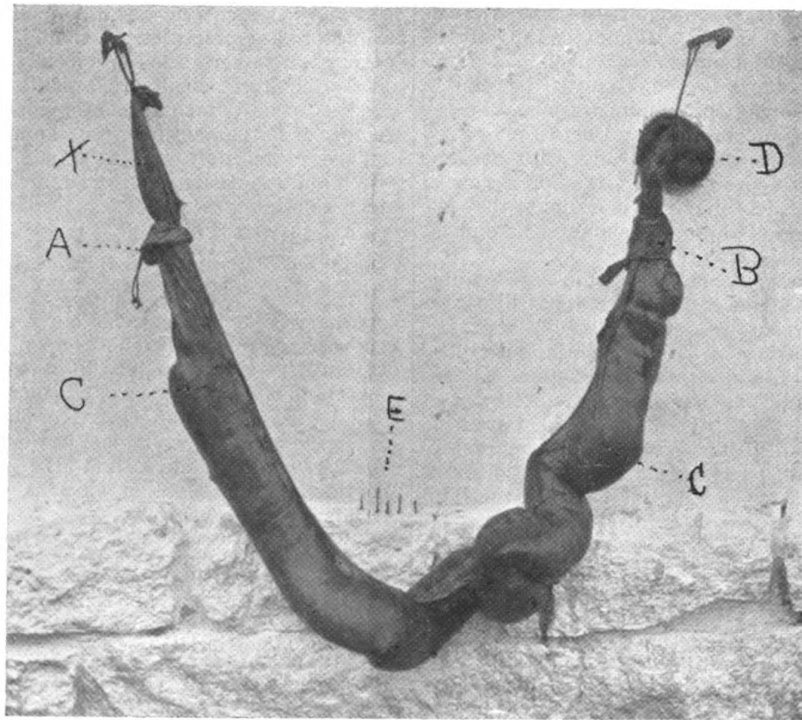

Subject.—Aged bay Waler mare, a polo pony, the property of an officer.

History.—No previous attacks of colic. Was sent to be tried in a chukker with a view to purchase on Sept. 22nd; polo ground six miles away. Whilst waiting on the ground previous to trial, suddenly fell down and showed spasmodic colic. Was got up after some difficulty, and sent to hospital, five miles from polo ground. Showed severe colic the whole way up.

drawn so tight as a twisted bowel. Rectum quite empty, no faecal matter met with full length of arm. Same symptoms lasted until about midnight when there was slight subsidence of pain, though appetite was wanting. Animal remained fairly quiet during the night, although dull symptoms were shown; all extremities very cold, and broke out into sweaty patches occasionally.

Morning, a little better. Temp. 103.4; very cold, occasional colicky symptoms, continual dull symptoms; no faeces passed, rectum still empty. Conjunctival mucous membrane remained practically normal throughout the attack; drank some water, but only chewed a little lucerne.

About 10 a.m., in spite of all treatment, fell down

EXPLANATION OF PHOTOGRAPH.

- X. Normal small intestine leading from duodenum to invagination.
- A. Commencement of invagination.
- B. Invaginating portion ending at B.
- C. Invaginating portion resected and end folded back to show invaginated portion.
- D. Terminal loop of invaginated portion.
- E. Some of the nails and screws found in double colon.

Symptoms.—When admitted about 6 p.m., severe acute spasms; no distension of bowel; temperature normal; no peristalsis audible, but borborygmus. Kept moving to prevent falling down as, if allowed to, endeavoured to roll on back. Given usual treatment, enemas and hose-pipe injections, but although straining only a small quantity of mucous discharged. Pulse frequent and small. Evidently obstinate stoppage of bowels; no peristalsis. Examined per rectum, and felt a cord-like, painful swelling, which did not appear to the touch to be

and died almost immediately. No Eserin was given.

Post-mortem, made about one hour after, revealed a ruptured stomach; the guts were then removed, placed on a table, and examination commenced from the rectal end. The floating colon was shrunken and quite empty. A big impaction encountered on entering the fourth division of the double colon. This consisted of a "dung-ball" about the size of a man's head containing gravel, some nails and screws. These latter were all of different shapes

and sizes, some of which are shown (*E*) in the photograph. Above this the contents were dry and hard, and towards the pelvic flexure another empty portion was found, and further on two more hard "dung bells," the size of cricket balls. In the 2nd portion the faeces were more or less normal and soft, and had evidently been acted upon by the medicines given, but at the caecal end of the first portion the contents were darkly stained with blood, as also at the upper end of the caecum. On entering the small intestines nothing but blood was found, and this was so for about 20 feet, when a very long telescopic condition of the bowel was discovered. The fore part had telescoped into the hinder. The invagination was removed after ligaturing with tape at each end, and the examination continued into the duodenum; the mucous membrane and external surface of which both showed inflammation. The stomach, except for the rupture in the greater curvature and consequent evacuation of the major portion of the contents, was normal. The invagination, which measured roughly 6 feet, was then photographed, and is explained in the accompanying photo; after which an endeavour was made to reduce the bowel to its normal condition. This was done after great difficulty, due to the mesentery attached to the invaginated portion. Both portions of the bowel contained blood, the invaginated portion showed strangulation, the mucous membrane being black in places. The invaginating portion was very much "kinked" towards the centre by the mesentery of the invaginated portion. After reduction and evacuation of the contents, the inner portion measured 7½ feet, and the outer portion nearly 20 feet, so that out of 72 feet of small intestine, about 27½ feet were involved in the intussusception.

I am indebted to Capt. Brachen, R.A.M.C., for kindly taking the photograph.

LYMPHO-SARCOMA IN THE DOG.

By E. WALLIS HOARE, F.R.C.V.S.

On September 4th an Irish water spaniel dog was sent for treatment; the following history was given by the owner.

The animal was two years and three months old, and about three months previously had suffered from a severe attack of distemper. On recovery from this, a peculiar appearance of the eyes was observed, and also the presence of a number of enlargements on the skin in various parts of the body.

On examination the eyes presented the appearance of acute conjunctivitis, the mucosa being very oedematous, and the eyelids much swollen. The eyes were very prominent, and the periorbital tissues swollen. A number of hard flattened enlargements were present on the skin in various regions, the largest being in the thoracic region.

The dog showed marked distress on being exercised, but while at rest appeared comfortable, and had a good appetite. Examination of the heart showed that the cardiac sounds were very indistinct and the impulse very weak.

On September 15th the animal was next seen, and all the phenomena found at the first examination were much more marked. Some of the tumours on the skin had commenced to ulcerate, the lymphatic glands all over the body were symmetrically enlarged, the inguinal glands being especially voluminous. The action of the heart was very weak, and distress was shown even while walking. The animal was destroyed with chloroform.

Autopsy.—The heart presented a peculiar appearance, as a large portion of the cardiac wall was of a firm white texture, a moderate amount of fluid was found in the pericardial sac. The liver was enlarged and congested. The spleen was normal. The abdominal lymphatic glands were moderately enlarged. I forwarded the heart, one of the affected inguinal glands, and one of the subcutaneous tumours to Mr. A. Leslie Sheather, M.R.C.V.S., who kindly examined them and reported the lesions as round-celled sarcoma.

The accompanying photo was taken on Sept. 15th.

CAVALRY COLLISIONS IN WAR.

In view of the remarks made on page 31 of the Statistical and General Report of the Army Veterinary Service for 1909, regarding the probable result of a charge made by cavalry, riding knee to knee, against another mounted unit riding in a similar manner, the following accidents are of interest, as they give support to the statement "that the impact, head to head or head to shoulder,

would mean the obliteration of the front rank of each side as completely as though they had ridden against a wall."

Quite recently the writer of this note was called to a parade ground where some mounted sports were being held preparatory to an assault-at-arms, and shown two horses lying dead within two yards of each other, and a third animal being led about with an attack of colic (?)

The two horses lying dead had accidentally been galloped into each other head to head, and just before the impact took place one of the horses raised its head, so that the full force of the collision was between this horse's mouth and the other's cranium. They both dropped as instantly as though they had been shot. The horse that had raised its head made an attempt to rise, which was no more than a movement, but the other animal did not even do this.

Post-mortem examination showed that one horse had been killed by its brain being penetrated by the upper incisors of the other, three of which were actually found broken off in the substance of the brain. The entrance had been made just above the brow band.

The other horse showed that three of its upper incisors had been broken off, and considerable hæmorrhage at the base of the skull was observed. The whole head was carefully boiled down, but no sign of a fracture was discoverable. The cervical vertebrae, similarly prepared, were also quite normal. The horse showing colic had been galloped into by another horse while it was standing still, and had been knocked over by the impact coming against its near side. This horse died two hours later, and post-mortem showed rupture of the stomach with its contents scattered through the peritoneal cavity.

The net result of these accidents goes to show that out of four horses colliding three were killed, and it enables one to form some idea as to what would be the result of cavalry charging cavalry. The case of ruptured stomach is the first one in the writer's experience that can be, beyond all doubt, directly attributed to external violence.

T. LISHMAN, Lieut. A.V.C.

Campbellpore, India.

ACORN POISONING.

Mr. Davis's note on the above subject is interesting. There is probably a reason for the fact he states in that acorns are more frequently gathered up in Germany and France than they are here. In Spain, too, quite a useful and widely employed food for pigs is provided by the oak trees. The outer husk of the seed is the part that produces the most mischief, and when prepared for food this is removed, and if the acorn is then dried its nutritive value is said to be greatly increased.

It is a matter for argument whether the fruit of *quercus pedunculata*, the common oak of England, Ireland, and Scotland, is not more poisonous than that of *quercus sessiliflora* which is found chiefly in North Wales and the hilly parts of the North of

England. Continental men recognise a sweet and bitter acorn, and it is the former that is the least harmful and most used as food. The forest acorn varies in nutritive constituents and in amount of production. Mature acorns must always be used. If not fully grown they are always dangerous. As a food they only appear to be useful for pigs and sheep, and then in small quantities.

G. MAYALL, M.R.C.V.S.

On Oct. 20th I was called to see 10 cows which had been eating acorns, 6 being aged cows and 4 heifers. They did not seem at all ill, but we gave each one a purgative dronch and they seemed to go on all right for a few days.

On Oct. 25th was called again, and found the older cows all right, but the heifers in a very bad state. Complete loss of appetite, shrunken eyes, occasional blinking, backs arched, lactation suspended. Two of them gradually grew worse, took to the ground, becoming comatose, in which condition they lingered for two days and died. Obstinate constipation at first, followed by strong diarrhœa.

Two of them are still alive, but won't eat, and they look like living skeletons. Acorns could be seen in the faeces when they were first taken ill.

J. H. PARKER, M.R.C.V.S.,

Faringdon.

THE YORKSHIRE VETERINARY MEDICAL SOCIETY.

A meeting was held at the Hotel Metropole, Leeds, on Friday the 27th October, when the President, Mr. J. W. Lazenby, Tadcaster, occupied the chair. Among the members who attended the meeting were: Messrs. H. G. Bowes, A. W. Mason, F. W. Clough, E. H. Pratt, S. Wharam, P. Deighton, Selby; S. E. Sampson, A. W. Noel Pillers, J. R. Simpson, W. A. Campbell, James Bell, J. A. Hodgman, Geo. Whitehead, J. McKinna, G. E. Bowman, W. Crawford, F. W. Pawlett, A. McCarmick, Treasurer, and J. Clarkson, Secretary. Visitor, Mr. R. R. Thompson, of Halifax.

The minutes of the previous meeting were read and confirmed.

CORRESPONDENCE.

The SECRETARY read letters of apology from Messrs. Abson, L. Jones, and Cockburn.

A notice had been received from the Royal Sanitary Institute as to the holding of their next meeting in July, 1912, in York. It was decided on the proposition of Mr. A. W. Mason to deal with it at the next meeting of the Society.

Mr. Shipley, of Great Yarmouth, Secretary of the Victoria Benevolent Fund, had sent a letter enclosing leaflets for distribution among the members of the Yorkshire Society, and asking for personal subscriptions, and that greater interest be taken in the work of the Victoria Benevolent Fund.

Mr. MASON and Mr. WHARAM both spoke of the deserving merits of the Fund, and suggested that all members of their Society should contribute something towards its maintenance, as at present it was not receiving that measure of support which was its due.

A letter was read from Prof. Woodruff in which he called attention to the fund opened by *The Veterinary News* for the purpose of assisting Mr. William Kirk in the appeal raised by the London County Council to

compel veterinary surgeons to pay for the use of the College crest.

Mr. McCARMICK proposed that £1 ls. be voted towards Mr. Kirk's expenses in connection with his defence, at the same time stating that he (Mr. McCarmick) would subscribe £1 ls. personally.

Mr. BOWMAN proposed as an amendment that they should make the subscription £2 2s., upon which Mr. McCarmick withdrew his suggestion in favour of Mr. Bowman's proposition.

Mr. BELL seconded the amended resolution, which was then carried unanimously.

The SECRETARY read a communication from the National Society in regard to the scheme for affiliation of veterinary societies to the National Society, and proposed that the Yorkshire V.M.S. give their formal expression of desire to be affiliated in accordance with the scheme.

Mr. WHARAM asked whether this should not appear on the minutes before it was approved, and thereupon Mr. Mason proposed it should be placed on the minutes and follow the proper course of procedure.

Mr. BOWES said he did not think there could be any good in delaying the matter. They had already approved of the scheme of affiliation several times, and he supported Mr. Clarkson's resolution that they do formally agree to affiliate. It was not a matter about which they were short of information. It had been discussed half-a-dozen times at the meetings of the Society.

Mr. MASON thought it would be advisable that it should be put on the minutes to come forward for discussion and approval at the next meeting. They would then be following the proper course, and they would be prepared for considering the matter.

Mr. CLOUGH asked whether the rules of the Society would interfere with the approval of the scheme of affiliation without due notice having been given.

This appeared to be the general feeling of the meeting, and the Secretary thereupon stated he would withdraw his resolution and forthwith give formal notice that at the next meeting of the Society the scheme for affiliation would be brought forward for discussion and adoption by them.

A letter read by the Secretary had reference to the death of the late lamented Prof. W. O. Williams, and after reading it he expressed the hope that a vote of condolence would be passed by the Society.

Mr. BOWES, in proposing a vote of sympathy with the bereaved family, said as an old student of the College of which Prof. Williams was at that time a tutor, he felt he was voicing the feelings of all of them when he said they would feel his loss as a personal loss. Particularly would they miss his genial company at their annual meeting and dinner.

Mr. WHITEHEAD seconded, and the vote was carried in silence, all standing.

The SECRETARY intimated that he had pleasure in announcing that at the spring meeting of the Society they were to have a paper from Prof. Ainsworth Wilson on "Sterility."

NOMINATION.

Mr. R. R. THOMPSON, Halifax, was proposed and seconded, and unanimously adopted.

FINANCIAL REPORT.

In presenting his financial statement for the year, Mr. McCarmick pointed out that they had over £40 balance at the bank, which was as nearly as possible the same amount as last year, in spite of the fact that they had had some very heavy expenses to meet during the last 12 months.

After a short discussion, the report and balance sheet was adopted.

ELECTION OF OFFICERS.

The retiring President, Mr. J. W. Lazenby, said he had the pleasant duty to perform of proposing the name of Mr. McCarmick for the position of President of the Yorkshire Veterinary Society which he himself was about to vacate. Mr. McCarmick was a well known worker, and it was the unanimous wish of the Council that he should be elected to preside over their meetings for the coming year.

Mr. WHITEHEAD, in seconding, stated that as the proposer of the name of Mr. McCarmick in Council, he had great pleasure in seconding the same resolution before the general meeting. They had heard the praises of Mr. McCarmick sung by the auditors in reference to his accounts, and he felt they would have the same sentiments to express with regard his chairmanship at the end of his term of office as president.

Mr. MCKINNA said he was glad to associate himself with the words of the proposer and seconder, and he was pleased that Mr. McCarmick had been prevailed upon to accept this, the highest honour their Society were in a position to offer to any of its members.

The resolution, on being put to the meeting, was carried with acclamation.

The retiring President then vacated the chair which was at once taken by the newly elected President.

Mr. McCARMICK thanked the members for the honour done him and the new dignity conferred upon him. He accepted the position with a great amount of diffidence because he felt he could not do justice to it. (Cries of "No, no.") However, he would do his very best. (Hear, hear). He was confident at any rate that he would have the support of the officers and Council, and with that help he hoped to be able to get along tolerably well.

Vice-Presidents.—Messrs. LAZENBY, DEIGHTON, and PAWLETT.

Treasurer.—Mr. Mason proposed, and Mr. Bowman seconded, the election of Mr. H. G. Bowes for the ensuing year, and this was carried without dissent.

Mr. BOWES, in acknowledging the vote, said he wished it to be understood that he was of course only intending to act as a temporary treasurer during the term of office of Mr. McCarmick as President.

Secretary.—On the proposition of the Chairman, seconded by Mr. Bowes, Mr. J. CLARKSON was re-elected.

Auditors.—Messrs. A. W. Mason and Wm. Crawford were re-elected.

Council.—The following six gentlemen were elected: Messrs. Bowman, McKinna, Ellison, Sampson, Wharam, and Whitehead.

EPIZOOTIC ABORTION IN CATTLE.

By E. H. PRATT M.R.C.V.S., Northallerton.

Mr. President and Gentlemen,—When your worthy Secretary sent me a wire asking me to give you a paper, I felt that everyone should try and do what he could for the benefit of our Societies, I felt bound to try and put my belief into practice. The only subject which I could think of for the purpose was "Epizootic abortion in cattle." This received the approbation of your Secretary; but the time being short for preparing anything for this meeting, I have simply tried to bring some of the main points forward so as to introduce the subject for discussion.

When one considers the enormous losses which are incurred by breeders, dairymen, and smallholders, I think that there is no need of apology for introducing the subject. One has known a case where a farmer has given up cattle breeding; of another who has abandoned the milk trade; and of one who has been practically ruined through this troublesome disease. The Board of Agri-

culture thought it advisable to have a Departmental Committee to enquire into the disease. The Committee carried out experiments, examined witnesses, and issued a most interesting report in which they recommended that action should be taken by the Board with a view to checking the disease. It is on that report that I have mainly based the few remarks which I have to make. I thought it quite probable that all the members would not have read it, and even if they have, it will be so much the better, because what I miss some member may bring forward. The report has been published, and the matter is of great importance to the country; therefore one would think that we, as a Society of veterinary surgeons, cannot do better than give it our careful consideration.

There appears to be no doubt that epizootic abortion in cattle is caused by a micro-organism, that the disease is contagious, and when once it makes its appearance amongst a herd of cattle it remains for a considerable time and inflicts great loss.

It has been proved that an animal may be infected by injecting natural virulent material or active cultures into the blood stream; by subcutaneous inoculation of considerable quantities of virulent material; by introducing virulent material per vaginam or by the mouth.

I have always been convinced that the bull was a great factor in the spread of the disease. Very unfortunately the committee were not able experimentally to prove or negative this theory. Only one satisfactory experiment in this direction was carried out, and it proved negative. The Committee state that "Without denying that the disease may sometimes be spread by coition, we think that nothing more than quite a subsidiary rôle in the spread of epizootic abortion can now be assigned to the bull."

One fact which impressed me with the idea that the bull was a carrier of infection, was a case where the first cow to abort, on a certain farm, had been sent to a neighbour's bull. The owner of the bull had had several cows abort. After this cow aborted the owner had a great many others follow.

The lesion of contagious abortion is confined to the uterus and its contents. "As long as the uterus remains closed, there is no fear of an infected animal spreading the disease by any other of its excretions to other animals. But once the contents of the uterus are discharged the infective material is liberated." This is a very important point when one considers that the course of the disease is slow. (The Committee found that "in ten experimentally infected animals which aborted, or which were killed when showing unmistakable symptoms of abortion, the average period between infection and the act was 126 days." The shortest period in any of these animals was 33 days, and the longest 230 days). The infection being confined to the uterus until the contents are discharged, gives one a chance to take precautions, because one knows the term when an animal becomes dangerous to others. Unfortunately all animals which abort do not exhibit premonitory symptoms, although many do. These can be taken and isolated and all discharges from the uterus can be treated with the object of preventing them infecting other cattle.

Externally the uterus of a pregnant cow affected with epizootic abortion seldom shows any departure from the normal, except that it may sometimes appear slightly more distended than one would expect for the period of pregnancy. Very exceptionally, however, slight oedema of the uterine wall is present in the neighbourhood of the neck. On cutting into the organ one finds between the chorion and the mucous membrane a variable quantity of exudate. It is particularly abundant around the cotyledons, and it may extend over the whole surface of the uterus and chorion, but apparently the extent of the area covered by it does not altogether depend upon the

length of time the animal has been affected. The exudate is usually of a light brownish yellow colour, which is possibly due to the chromogenic character of the microbe. Sometimes, however, it is a dark chocolate colour, due probably in some cases to admixture of blood, and in other cases to the oozing of fluid from the muscles of a mummified fetus. Its consistence varies from that of fluid pus to that of tough dough. Frequently it is so glutinous that it is difficult to remove small portions with a platinum needle. If a portion of the fluid exudate be placed in a test tube and allowed to stand for some hours, it separates into a lower portion of yellow solids, and an upper portion consisting of a dirty grey liquid. When the exudate is removed from the surface of the uterine mucous membrane the latter shows no microscopical lesions.

In advanced cases many of the cotyledons are softer than normal, and they may even be pulpy. In such cases the cotyledons have a distinctly yellow necrotic appearance, but no sign of necrosis is to be found on examining sections of the tissue. The sub-choroidal tissue of the fetal membranes is in some cases oedematous and has an appearance very like mucoid tissue. In quite a number sent up to the Board's laboratory, portions of the chorion have been found thickened and of a leathery appearance.

The fetus may, or may not, be altered. Out of 19 fetuses taken from experimentally infected animals, seven were found in which distinct pathological changes had taken place, that is to say, in 36·8 per cent. The changes in the fetus seem to depend on the length of time it has been dead. In no case in the cow was the fetus putrefying *in utero*. The fetus may be quite normal in appearance, and up to time as regards development. Sometimes the tissues are oedematous, and occasionally the oedema is blood tinged. Not infrequently the only alteration found in the fetus is dropsy of the abdomen, or it may be of the chest. The umbilical cord is frequently, though not always, dropsical. Sometimes the fetus is on the way to become mummified. In such cases the fetal membranes are closely adherent to it, and when one separates them one removes also what is left of the fetal skin, exposing a dark brownish-red and distorted mass of bony and muscular tissue in different stages of desiccation.

Of course before going in for any legislation with the object of combating a disease, it is most necessary to be able to prove that one's diagnoses are correct. This was a point which in the past appeared to me to offer great difficulties. Because if an owner exposed a cow in a market and an inspector saw her and suspected that she had calved prematurely, how was he to prove whether his suspicions were correct or not. We are now told that "It is an easy matter to identify the characteristic clumps of abortion bacilli in microscopical preparations made from the uterine exudate discharge immediately before and after abortion." The bacilli stain admirably with methylene blue or diluted carbol-fuchsin. They do not retain the stain when treated by Gram's method, and they are not acid-fast.

"If a suitably stained preparation made from the uterine exudate of an affected cow be examined under the microscope, a large number of white blood corpuscles and catarrhal cells from the uterine mucous membrane can be seen. Between the cells there are numerous single bacilli, which are mostly of an oval shape; some, however, are distinctly rod-shaped, like the tubercle bacillus, and collected into dense groups or colonies. Some of these groups look as if they were bounded by a cell membrane and give the impression of being contained inside tissue cells. In many cases, however, they look simply like collections of agglutinated bacilli. Lying amongst the smaller elements of a colony one sometimes sees very large oval elements which take the stain very deeply."

As a rule the majority of the bacilli are between one and two microns in length, but many are less than one micron. The longest measure about three microns. Tubercle bacilli, as you are aware, are from three to four microns in length. The committee prepared a material analogous to tuberculin, which they have called "abortin." When abortin was injected intravenously or subcutaneously into a cow which had previously aborted or which had been infected with the disease, a temperature reaction usually followed.

In animals not infected the temperature might rise to 103, but in infected ones the temperature would rise to 104, 105, and 106 F., commencing at the fourth hour and lasting until the fourteenth. Experiments with a method of diagnosis based on what is termed "fixation of the complement" for the purpose of diagnosing the disease in apparently healthy pregnant cows, gave promise of success. This method appears to be too complicated for anyone to adopt except an expert bacteriologist. I think, therefore, we need not go further into it at present.

If these methods eventually prove reliable, most useful weapons will have been prepared for commencing the attack upon this troublesome disease, because without something of the kind it is quite impossible to inspect a herd of dairy cattle and form any opinion as to what percentage of the animals are infected with the disease or not. Or to be shown an animal say a week after she has calved and be told that she calved before her time; then to be asked the question "Was the premature birth due to contagious abortion or accident?" How is a man going to give an opinion which he can defend with any assurance of being right? With no other evidence, I fail to see how he can.

An animal which aborts through the action of the abortion bacillus gains a considerable amount of immunity, but this immunity is not constant; it is known that some cows will abort two or three times in succession.

Experiments were carried out with a view of producing a degree of immunity which would be useful in practice, and encouraging results were achieved. It was found that large quantities of virulent cultures or pure virus could be injected into non-pregnant animals without serious consequences. Two maiden heifers were injected with 125 c.c. of a culture from the uterine exudate of a heifer which had been experimentally infected and slaughtered before abortion had taken place. The heifers which received these injections subsequently became pregnant 148 and 142 days respectively after immunisation. The first one received intravenously an injection of virulent uterine exudate emulsion 40 days after becoming pregnant. She was killed and found free from infection 112 days after the test inoculation.

The second heifer's immunity was tested by giving enormous doses of virulent exudate both by the mouth and vagina 36 days after becoming pregnant. She was killed and found free from infection 122 days after receiving the first infecting dose.

One experiment was carried out to test the result of carbolic acid treatment. The result of the test showed the treatment to be a failure.

The injections of dead liquid cultures were undertaken with a view of finding a curative agent. Three animals were inoculated intravenously with exudate to infect them. From 14 to 52 days afterwards these animals received every week for ten weeks large doses of dead liquid culture by subcutaneous injections. One of the heifers aborted about the average time after infection (123 days), the other two were slaughtered 112 and 113 days after infection and found healthy.

The prevention of epizootic abortion amongst cattle naturally divides itself into two parts. One is private effort and the other State interference. There is no

doubt that much can be done privately to get rid of this troublesome disease, but if an owner of cattle is obliged to keep up his stock of breeding or milk cows by buying in the open market he has a very difficult problem to face, because he must be always liable to get an infected animal and so bring the disease on to his farm.

Legislative measures require very great care in their framing, because the disease appears to be so widespread that any severe restrictions would paralyze the cattle trade and the dairy industry of the country. As we have seen, the disease takes a long time to develop; therefore if animals which had been exposed to infection were placed under restrictions the inconvenience of isolating them would last a very long time.

To commence to slaughter out would be, on account of the large numbers involved, ruinous to the cattle and dairying industries, and the cost to the State would be enormous. One thinks that these considerations must have been evident to the Committee after investigating the disease and hearing the evidence which they got from a large number of agriculturists representing the various agricultural and cattle breeding societies from different parts of the country; because they only recommend that legislative measures should be taken at present against cows which have aborted.

They say "We therefore recommend that as a preliminary measure, epizootic abortion in cattle should be dealt with under an Order of the Board of Agriculture and Fisheries requiring:—

(1) Compulsory notification of suspected cases of the disease.

(2) Veterinary inquiry to establish the existence of the disease.

(3) Temporary isolation and restrictions on the movement of any cow that has recently aborted.

"We also consider that in the event of effect being given to the above recommendations, such measures as may be thought necessary should be taken to avoid the possible introduction of infection in cows imported into Great Britain from Ireland, the Channel Islands, and the Isle of Man."

As to private effort, my experience is that a large number of breeders of cattle and dairymen will take advice, and carry out all kinds of experiments to get rid of the disease when that advice is given gratis, by those who know as little or less than themselves.

I think that private effort properly directed and thoroughly carried out can do a great deal towards ridding owners of cattle of the complaint, but as I once told a client, there is some trouble in carrying out measures which are effective.

Perhaps the best way to bring this forward is to give one's experience in dealing with the disease, in so doing perhaps others will give us their experience when the time comes for the discussion which I hope will follow.

One owner came and said that his cows were picking their calves, could anything be done to help him out of the difficulty, which if it continued would, to use his own words, break him. One cow had aborted a day or two previously and had retained her placenta. This he was advised to have taken away by hand. That was done, and the cow and all the others which had previously aborted were well irrigated with an antiseptic solution injected by means of an enema pump. Antiseptics were supplied and also a home-made injection tube to be used a few times for the cows which had aborted. A syringe was supplied for use on the bull and instructions left for disinfecting the organs of the bull after every service. The byre was thoroughly cleansed and disinfected, the man doing his work thoroughly. No cows were advised to be sold, but all kept and put to the bull. The following season the owner was rewarded by every cow proving in calf and carrying their calves to their full

time. He still keeps a supply of antiseptics and uses it for the bull. This case occurred a few years ago, and he has not been troubled with the disease since.

Another owner sought advice, and said that he had had several cows abort; he had sold them off, but things were no better; even heifers which he had tried to keep isolated had aborted. He was advised not to sell any more but try disinfection. Unfortunately he had no bull of his own. In a while he reported that he could not get his cows to prove in calf. Consequently when they came in season, instead of being sent to the bull, I went to his place and irrigated the uterus to the best of my ability with an antiseptic solution. It is not an easy matter to do this because the os uteri is very small and will not allow the nozzle of the pump to pass, but by a little manipulation it can be dilated somewhat, and I think that by holding the nozzle against the os some fluid must be forced into the uterus. However, this was done, and the cows were served at the following period of oestrus. Now we think that the trouble has been got over, for the cows so treated are carrying their calves the full time.

One has found that other cows which have aborted, and could not be got in calf, have proved pregnant through this treatment. One would like to know if others have found the same difficulty of cows not breeding after abortion, and what remedy they have found successful in treating it.

In reading the report of the Committee one was surprised to find that the irrigation of the uterus was not recommended. It says "With the act of abortion the greater part of the uterine exudate is immediately ejected. That some of it remains behind for a short period is certain, since we were able to demonstrate abortion bacilli in material obtained from the vagina of a heifer three days after she had aborted. On the other hand no abortion bacilli could be found in the uterus of a heifer a month after she had aborted. It seems probable that, as a rule, the genital organs cleanse themselves by natural means a comparatively short time after abortion has taken place. Almost immediately after abortion and expulsion of the membranes the uterus contracts, and its internal surfaces come into apposition. Its condition is such that it would not be possible to force fluid into it with a pump from the vagina. Apart, then, from the probability that disinfection of the uterus by antiseptics is not necessary to rid the organ of abortion bacilli, we are of opinion that it is futile to attempt it by irrigation methods."

The Committee think that for hygienic and therapeutic reasons the genital passages should be cleaned twice a day as long as there is any discharge. They are of opinion that it is seldom necessary to continue the injections for more than a month, and that after three months there should be small risk in putting the cow to the bull. Professor Bang, in his admirable paper which he gave to the National Veterinary Association at Liverpool in 1906, says "After abortion the womb of the cow must be carefully cleansed and disinfected. If the after-birth does not come it ought to be artificially removed (this ought to be done on the first day) and the womb should be carefully rinsed with some antiseptic solution several times in the first days, as long as it is possible. A careful disinfection of the womb is not only important as a way of destroying the contagium in order to prevent infection of other cows, but it is also the best way to protect the cow against sterility, and against abortion in the next pregnancy."

On this practice, and in connection with infections supposed to be spread by the bull, Professor Bang quotes a case reported by Mr. Poulsen (Ringsted):—"A farmer who owned 16 cows, amongst which abortion had never occurred, nine years ago allowed seven of his cows to be served by a bull at a neighbouring farm where abortion had prevailed for some years. All these

seven cows aborted, and no others. When these cows began to show signs of impending abortion they were immediately removed from the byre and put into another stall. By all seven cows the after-birth was retained, and Mr. Poulsen therefore had it removed by hand within 24 hours. The removal was complete in the case of six of the cows, but not in the seventh, which became emaciated and was soon afterwards sold. After the removal of the after-birth the cows were daily washed out with carbolic water, and they were not readmitted to the byre until some considerable time afterwards, when they appeared to be entirely free from discharge. During the following year the six cows again became pregnant and carried their calves the full term. No case of abortion has since occurred in this herd. "I think," says Prof. Bang, "every one will admit that in such a case the bull has been the carrier of the contagion." He quotes the case as being "an excellent example of a successful rational prophylactic treatment of a new imported contagious abortion."

One would think that we now know sufficient of contagious abortion to recommend with confidence measures being taken to prevent the spread of this disease, which would not be unduly harassing to the trade, nor too expensive for the State to carry out. We believe that both the owner and the State would greatly benefit. To stimulate discussion on the subject I would offer the following suggestions:

1. That contagious abortion in cattle causes very serious loss to the community, therefore it should be scheduled by the Board of Agriculture, and steps taken under Order for its prevention and eradication.

2. All cows which abort or calve more than a month before their due date should be reported.

3. A veterinary inquiry should then be made into the matter, and if it were found to be a case of contagious abortion the animal should be treated under direction by a State paid veterinary surgeon who would arrange for its isolation and for disinfection of the premises. The whole to be carried out according to principles laid down by the Order.

4. If abortin proves to be a reliable diagnostic agent its use should be made compulsory, and no cows which had been exposed to infection should be allowed to be sold which reacted to it, unless they were branded.

The third proposal, that cows which have aborted should be placed under the charge of a veterinary who should be remunerated by the State, will, one ventures to think, meet with your approval. Because, if the animals are to be placed under any restrictions, some one should see that they are carried out. Who can be more suitable to do this than men who have a grasp of the whole subject, and who understand the why and the wherefore.

It has been demonstrated that good results have followed treatment, therefore whilst the veterinary surgeon was visiting the place to see that the Order was properly carried out, he could at the same time give practical help and advice, which should be appreciated and be good compensation for any inconvenience the owner was put to on account of the Order.

I think, gentlemen, I have said enough, and thank you for your kind attention. If you criticise please remember that these notes—or perhaps I should say collection of extracts—was run together hurriedly to oblige your Secretary, therefore deal kindly with the errors and correct them by giving us your own experiences. If you do so we are sure to have a good discussion, and the object one had in view in bringing the subject forward will have been attained.

DISCUSSION.

Mr. SAMPSON gave it as his opinion that it would be better to call the disease which formed the subject of the paper, not *Epizootic abortion* but *Specific metritis*.

Such a name would convey the idea that it was not to be confounded with accidental abortions which they came across. It was most important that they should employ their efforts to find some adequate remedy for the disease, for the spread of it in a herd meant a great loss to the owner. First there was the loss of the calves, in addition to that a cow which had aborted only yielded half the quantity of milk, though it was being fed at the same rate as other cows. That meant a great national loss when they came to think of the prevalence of the disease, and it was a subject, he submitted, which was ripe for investigation and also for legislation. He was surprised that the Commission referred to by Mr. Pratt in his paper, which was appointed to inquire into the matter, had not given it as their opinion that the bull was the carrier of the disease. He himself should certainly think so. He knew of a case where a strange bull had served some cows in a herd and subsequently the disease had broken out where it had never been known before. Another point in Mr. Pratt's paper was in regard to injection of the uterus. Nine out of ten times after an injection had been made, there was some fluid left down in the horn of the uterus which it was impossible to get out. This acted as an irritant and upset the cow badly. For his own purposes he had lately resorted to the use of pessaries which caused less irritation to the cow, were easily put in, and answered the same purpose as an injection. Pessaries had the great advantage of not filling up the uterus with any foreign material; they dissolved and nothing was left. Mr. Sampson finally referred to the fact that he could generally tell by the *feel* a cow which had aborted from one which had not. He did not know whether veterinary surgeons had experienced this, but he found he was able to distinguish by the sense of touch in this way.

Mr. CLARKSON agreed with Mr. Sampson that the bull was a very large factor in the spread of the disease. He was rather surprised that the Commission had not laid more blame to his score than they had. As they knew, amongst small holders one bull had to serve a large number of farmsteads and in this way, he thought, the disease was spread. As regards injections *versus* pessaries, he there again found himself in agreement with Mr. Sampson. He did not think so much of irrigation, because it was not so clean an operation as the use of pessaries. When he did make an injection he always used two tubes; one for injecting and one for the outflow.

Mr. CLOUGH said he would like to endorse the remarks of the two previous speakers as to the blame to be attached to the bull in the propagation of the disease. He knew of a case where a bull had served cows on a farmstead six or seven years ago, and that farmer had had abortion in his place ever since. The farmer himself traced it to the bull. One peculiarity which he (Mr. Clough) had noticed about these cows was that after they had come to their full time they kept their afterbirth. As to injections, he had stopped injecting. There was always a considerable amount of straining with the cows, and he had seen them put the vagina down, and the rectum down, as a consequence of the operation. He was certainly in favour of adopting the alternative course of using pessaries.

Mr. BOWES said as a town practitioner he had not had any very great experience of epizootic abortion. He did not think however the Commission had conducted a sufficient number of experiments to disprove the agency of the bull in spreading the contagious disease. He liked pessaries in preference to injections. He thought it a much cleaner and more satisfactory method. Whether it would apply so well in contagious abortions he did not quite know, because the uterus was pretty well closed up and the pessaries would have to be small. The majority of the farmers were firmly convinced of the efficacy of carbolic acid, especially in districts in Scot-

land, and they certainly had some cases which appeared to speak very highly for carbolic acid. If it had been for no other purpose than convincing the lay mind, he thought the Commission ought to have conducted further experiments. The Commission had not believed in carbolic acid at the outset, and they had not appeared to think it worth while to deal with the matter at all. He did not quite agree with Mr. Sampson in his suggestion that the disease under discussion should be called Specific metritis. It was a catarrhal condition, but scarcely metritis; if so, not of a very acute type. It was difficult to decide from a diagnosis whether a case was an ordinary abortion or a contagious abortion. In the cases cited by Mr. Pratt, when abortin was injected, there was a reaction after the cows had aborted. Did the same apply if they were pregnant.

Mr. PRATT: They are supposed to do so.

Mr. WHARAM spoke of the difficulty of diagnosis. He agreed with Mr. Bowes that it was not easy to diagnose a case of contagious abortion when first seen. With regard to scheduling, he did not think the disease was so prevalent as it used to be. He thought the sanitary arrangements made by most breeders had tended to reduce the number of contagious abortions. The more frequent use and knowledge of antiseptics had, in his opinion, much contributed to reduce the extent of the disease. That was all done by individual effort, and the fact of so much having been accomplished in this way would no doubt retard any action taken by the Government. In reference to the manner in which the contagion enters the body of the cow they knew it might be ingested, or might enter *per vaginam*, and no doubt the bull was often responsible for it. He had not the slightest doubt that the disease in most cases - although the Commission did not appear to think so - was propagated by the bull. To remove the cleansing the same day as the cow aborted would be impossible in many cases. There was a very great danger in washing out many of these animals. It was much safer to use pessaries, and in that way a fairly strong antiseptic might be introduced which would do all that was necessary. He thought with good veterinary surgeons practising in the country districts they would entirely get rid of the disease.

Mr. PRATT, in replying to the discussion evoked by his paper, said most of the gentlemen who had spoken appeared to think that the bull was the carrier of the disease in the majority of cases. That was his view, too, and he was glad to see that owners of bulls were getting very particular as to what cows they allowed their bulls to serve. With regard to the relative merits of the alternatives of washing out the uterus and the employment of pessaries, the latter had never seemed to appeal to him so much as irrigation. A pessary might sink away down into the bottom of one horn of the uterus, and they did not appear to him to have that cleansing effect that a pump had. By the irrigation method, if one bucketful was not enough, two or three might be used. He himself had first used Jeyes' fluid but had found that sometimes the cows strained most awfully. He had begun to use Chinosol now, and found it very efficacious. He had never tried to draw it out again, but rather liked to see it left in, as it mixed with the tissues and, in his opinion, exercised a purifying effect on the cow. At any rate it did no harm.

Reference had been made to the use of a curative agent. Abortin was not brought out as a curative agent, but simply as a diagnostic agent. The Committee experimented with dead bacilli as a curative agent. Animals were infected and large quantities of dead cultures were inoculated for about seven months with a view to preventing the disease. In two cases the experiment was successful, and in one case the cow aborted. As regards abortion not being as prevalent as it used to be, unfortunately it was at any rate very common, and it

was no doubt spread by the fact that a farmer, when a cow of his aborted, often immediately sent it to the market, and if a man bought it in good faith he got an aborting cow.

Mr. BOWMAN said he would like to ask Mr. Pratt what he considered was the best method of disinfecting the bull.

Mr. PRATT replied that he had instructed his clients to dissolve Chinisol tablets in water, take an enema pipe, put the nozzle into the sheath of the bull and pump in until the sheath was full. Of course, added Mr. Pratt, with a smile, you have to look out for "number one," but it was not often that the bull was refractory. They got used to it.

On the proposition of Mr. Bowes, seconded by Mr. Clarkson, a hearty vote of thanks was given to Mr. Pratt for his instructive paper which had led to such an interesting discussion.

Mr. MCKINNA suggested that before the meeting closed a vote of thanks should be given to their late President, Mr. J. W. Lazenby, who had filled the chair with dignity and great success, and under whose genial chairmanship they had all enjoyed sitting. It was with regret they saw his term of office come to a close.

This was seconded by Mr. Bowes, and carried unanimously.

Mr. BOWES proposed, and Mr. Wharam seconded, "That the President be empowered to nominate Mr. Clarkson as the Yorkshire Veterinary Society's candidate for a seat on the Council R.C.V.S. as soon as nominations are invited." This was carried.

Mr. NOEL PILLERS suggested that the item in the agenda "interesting cases" be in future taken before the paper and discussion, as otherwise it meant, as they had so often experienced, that this item of the agenda was not reached until the end of the meeting when members were anxious to leave, so that the consideration of such cases was cut short in a very hasty manner. In the case of other societies he quoted, "Interesting cases," was taken before the paper.

Mr. SAMPSON supported Mr. Piller's suggestion, but no action was decided upon.

Mr. PRATT showed specimens under the microscope illustrative of his paper, and these were inspected by several of the members.

Afterwards those present adjourned to an adjoining room of the hotel where they were entertained to tea at the invitation of the Leeds members of the Society.

Actinomycosis in Norway.

Professor Harbitz and Dr. Backer Grøndahl have recently published (*Norsk Magazin for Lægevidenskaben*, June) an account of the incidence of actinomycosis in Norway, where this disease has lately been carefully studied. The first case published in Norway dates from 1887, and for many years afterwards the disease attracted scant attention. More recently a number of cases have been reported from different parts of the country, and at the Pathological Institute in Christiania 87 cases have now been studied, with special reference to the source and course of the infection, as well as to the varieties of fungi found in different lesions. The seat of infection was the cervico-facial region in 39 cases, the lungs in 20, the abdomen in 26, and the skin in 2. The disease was twice as frequent in men as in women. Its incidence was not greater than usual in the months August to January. Many of the patients were town-dwellers, and most were recruited from the eastern and southern provinces, the west coast, including Bergen, being extraordinarily free from the disease. In the cervico-facial region the disease is chronic but benign and tends to spontaneous recovery.

All the 39 patients so affected recovered. The primary focus in this class could seldom be found, but it was twice localised in the tongue, once in the submaxillary gland, and occasionally there was a history of aching gums early in the disease. In the lungs the disease was invariably fatal. The primary focus was in the pulmonary tissue; infection from the oesophagus to the lungs, as described by some writers, was never observed. Usually the first sign of the infection was a bronchopneumonia. In the abdominal form 20 per cent. recovered. The primary focus existed in the appendix in nine patients, and this was also probably the case in five others. Of these cases the appendix was usually scarred, or it presented a perforation leading directly to an abscess. The spread of infection may be intra or extra-peritoneal. In the former case it often involves and perforates the bladder, when the fungi may be found early in the urine. In the latter case it may track up behind the diaphragm, and an empyema may be the first sign of an abdominal infection. Of the two cases of primary skin infection one occurred in a man who worked in a corn-field without stockings. He died in spite of radical treatment, including amputation at the thigh. Passage of the fungi by the blood stream was occasionally observed in the later stages of the disease, when distant organs such as the brain and the lungs became involved, but spread of infection by the lymphatic system was never seen, and the authors emphasise the diagnostic value of this point. In 16 cases of actinomycosis hominis they succeeded in isolating one and the same facultative anaerobic fungus differing from that which most German writers have described as pathogenic (Boström's type). It also differed from every aerobic type cultivated from various plants. An identical growth was once cultivated from bovine actinomycosis, seven cases of which were examined. Professor Harbitz and Dr. Grøndahl consider it probable, but not proved, that human and bovine actinomycosis are caused by the same or by closely allied fungi. Numerous attempts were made to isolate from corn, straw, hay, and the air the same anaerobic fungus; none but the familiar aerobic fungi could, however, be found, and these were not pathogenic to rabbits or guinea-pigs, nor could any progressive actinomycotic inflammation be induced. The writers locate the site of infection either in the lining of the respiratory tract or in the digestive tract which has been infected by swallowed matter. Less is known of the source of infection. Infection from cattle to man, or from man to man is not proved and is highly improbable. Probably the pathogenic fungi are derived from various plants; but how and where they live in nature is unknown. J. H. Wright has suggested that the fungus pathogenic to man and cattle does not exist elsewhere, and that it is often present in the mouth of man, becoming pathogenic with trauma. This theory is worthy of consideration, but it requires further support. The diagnosis of actinomycosis by complement fixation or agglutination was found by the writers to be impossible, and owing to the capriciousness of the disease and the variability of its course, it is difficult to estimate the value of the various remedies in use, including potassium iodide. Twice the writers used a vaccine made from sterilised cultures of the fungus; the treatment was quite negative in one case, and in the other case, which presented advanced abdominal disease, there was considerable improvement. The perusal of this interesting paper leaves the reader with the unsatisfactory impression that there are vast and numerous lacunae in his knowledge of a disease which has commonly been treated by text-books as a cut-and-dried subject.—*The Lancet*.

* As Diseased or Exposed to Infection

Veterinary Training and the Public Health Service.

The vast extension of the domain of pathology in recent years has brought into clear relief the intimate relationship between human and veterinary medicine. Particularly has the new science—bacteriology—contributed to this, not only by making plain the practical identity of many disease processes in the animal and the human being, and rendering possible the study of the one through the other, but also by demonstrating hitherto unsuspected channels of infection. As a consequence of this new science, exacting as it does considerable technical training and the command of adequate laboratory facilities, a specially trained set of medical practitioners has arisen adequately equipped to examine the problems of public health and preventive medicine. When investigating defects in human habitation, clothing, food, and occupation, they are necessarily driven to a consideration of matters affecting the domestic animals that come into relation therewith in various ways. The problem of tuberculous cattle, for instance, is closely interwoven with that of human tuberculosis. The need is continually becoming more obvious, therefore, for a class of veterinary sanitarians, highly trained in scientific research methods, to approach from the animal side the solution of those common problems that are already being vigorously attacked from the human side by the medical officers of health. This need recently received forcible expression at the hands of the President of the Faculty of Physicians and Surgeons of Glasgow, Dr. David N. Knox, in his address at the opening of the Glasgow Veterinary College. After pointing out that no gulf existed between human and veterinary medicine, for both were based on the same scientific principles and threw light each upon the other, he urged upon the governors of the College, the

veterinary profession, and the students the importance of the study of bacteriology. Referring to a feeling that seemed to be growing in the veterinary profession that veterinarians should be appointed meat and milk inspectors, he said that scientific laboratories were an absolute necessity for efficient inspection, and he proposed that there should be evolved a class of veterinary surgeons especially skilled and capable of working in such laboratories. For some time to come he feared that such officials would for the most part have to be sought among medical officers of health, until the veterinary profession awoke to the necessity of providing the scientific training required. Failing the establishment of a veterinary diploma in public health by the Royal College of Veterinary Surgeons, he offered as an alternative suggestion the establishment by the Glasgow Veterinary College of post-graduate courses in public health, which would involve the establishment of a public health laboratory, where special instruction in chemistry and bacteriology might be given with a practical examination at the end of the course. It seems certain that an increasing scientific equipment of veterinary sanitarians would secure valuable co-operation between the medical and veterinary professions in the field of public health.—*The Lancet*.

Veterinary Surgeons and Meat Inspection.

We have received the following interesting communication from Principal McCall, of the Glasgow Veterinary College:—

I am pleased to inform you that the provisions for the instruction of veterinary students in bacteriology and meat inspection which were foreshadowed by Dr. Knox in his introductory address to the students of this College are now in operation, and have been in operation, since the year 1895.

In that year the Council of the Royal College of Veterinary Surgeons (of which body I am a member, and have been for upwards of 30 years) advanced the period of study from a course of three years to one of four years, and added to the subjects of study bacteriology and meat inspection.

In this College all students studying for third professional examination are required to attend (1) "A course of not less than 80 lectures on the morbid anatomy and pathology (including bacteriology) of the domesticated animals," (2) "A practical course extending to not less than 40 hours' instruction on the morbid anatomy, pathology (including practical bacteriology) of the domesticated animals."

On the termination of his third session's study the student is examined on the above subjects by the examiners of the Royal College of Veterinary Surgeons (no Professor or Lecturer in any of the Colleges is allowed to act as an examiner).

Those students who pass this examination receive in their fourth year instruction on practical meat inspection at the Moore Street abattoir during the session, and on its termination they are again subjected to a practical test conducted by another set of examiners, also appointed by the R.C.V.S., and, if successful, receive the diploma of the Royal College of Veterinary Surgeons.

The students of the London, Edinburgh, Liverpool, and Dublin Colleges receive similar instruction, and are examined by the same examiners, so that more cannot be done than is being done to make veterinary surgeons competent meat inspectors, and I have no hesitation in saying that the members of the Royal College of Veterinary Surgeons who have received their diploma since the year 1895 are competent to act as meat inspectors, and have received a more extended course of theoretical and practical instruction in meat inspection, than the members of the medical or any other profession.

Dr. Knox was so far correct in stating that "he did not take the view that a veterinary surgeon *per se* was of necessity the best qualified meat inspector"; but a veterinary surgeon with the training he now receives, and has received since 1895, in pathology, bacteriology, practical meat inspection, not to speak of anatomy, physiology, chemistry, botany, veterinary medicine and surgery, etc., etc., must of necessity now be the best qualified inspector of flesh foods.

I also observe that "The Raider," under "Evergreen," remarks "that there is just one outstanding defect in the Veterinary Colleges. There are not sufficient students on the benches to make them flourish." But I cannot admit that it is the fault or defect in the Colleges that the number of students attending all the Colleges are reduced by one-half, or that the Colleges are not flourishing—*i.e.*, doing good work.

In 1895 the Council of the Royal College of Veterinary Surgeons advanced the matriculation or general educational examination to the standard required for admission to the Medical Colleges. This knocked off at one blow one-half of the students formerly admitted. Then the period of study was raised from three to four years, with an advance of fees amounting to £20 on the fourth session, and we were recovering from these blows; but now we are in the throes of the motor craze, and back to where we were in 1895 in respect of entrants. No one, however, can say that the Colleges are to blame for the paucity of students, and if by "not flourishing" it is meant that the Veterinary Colleges are not paying their way in fees obtained from the students, that will apply to all the Universities and Medical Colleges in the country, as also the Technical Colleges and the Agricultural Colleges; and if we apply to the students of the two last-mentioned institutions the same educational tests before admission as are applied to the students of the Veterinary Colleges, I hesitate not to say that two-

thirds of the entrants to these institutions will be unable to gain admission.

I enclose herewith a copy of the prospectus of this College, and by a reference to its pages you will obtain ample corroboration of the statements I have made as to the facilities afforded students in acquiring a knowledge of the subjects of bacteriology and meat inspection.—*Scottish Farmer*.

Death from Glanders—Inquest.

At the Congregational Institute, Bexley Heath, on Wednesday, Aug. 23, Mr. H. B. Sewell, the Coroner for the district, conducted an inquest concerning the death of Herbert John McGill, 26 years of age, the son of George McGill, contractor, of 36 North Street, Bexley Heath.

Mr. H. J. Bracher, solicitor, of Maidstone, was present to represent the Kent County Council.

George McGill, carman and contractor, of 36 North Street, Bexley Heath, stated that the deceased was his son, who lived with him. His age was 26 years last birthday, and he was employed by witness as a carman. The deceased enjoyed very good health, and had nothing the matter with him since he was a baby. The deceased sometimes assisted in horse slaughtering, but did not do much at it. He was engaged on July 31st by Mr. Hoare, Inspector under the Diseases of Animals Act, to assist in slaughtering a horse that had glanders, but in the meantime it died. His duty then consisted of carting the carcass from Mr. Williams' stable at Bexley to the grave, to prepare it for the veterinary surgeon to make a post-mortem examination. The grave was at the back of Oxford Place, close to the stable. The examination was conducted by Mr. Robards. Witness was not present at the examination. The deceased came home about six o'clock on July 21st and said that he had cut his arm. It was bandaged, and deceased would not let anyone touch or look at it. He said that Mr. Robards had dressed it. The deceased explained that the knife with which he was cutting the tongue out slipped and cut his arm. The next day witness saw the arm, and there was a small flesh wound that did not look very bad. Deceased went out on the Tuesday, and on Wednesday he did no work, and, as his arm pained him, he went to Dr. Leslie. Deceased bathed and poulticed it as ordered, and went to the doctor every day to the following Monday, when he "lay up." Death took place on Monday, August 21st, at seven o'clock in the morning. Deceased had assisted at post-mortem examinations since he was 14 years of age. He was a sober lad, and took his own knife on the occasion in question.

Mr. Bracher: Mr. Hoare came to you, to engage you, didn't he?—No, he wanted my other son, but he couldn't go, and I said, "There's my son Herbert," and he said to him, "You will do, you come."

But his conversation was with you?—Partly with me, and partly with my son.

He has paid you for your son's services?—He has paid my wife.

Frank Walter Robards, veterinary surgeon, of Camden House, Dartford, Veterinary Inspector to the Kent County Council for the Dartford district, deposed that he was making a post-mortem examination on a horse supposed to have died from glanders, on July 31st. He understood from Mr. Hoare that young McGill would be there to assist. The horse was just behind the Oxford Mews, Bexley. Deceased was present when witness arrived, but had not done anything beyond carting the carcass to the place where it was to be buried. Deceased took out the viscera, lungs, and the trachea and larynx. Whilst he was taking out the trachea, which was a bit awkward to do, the knife slipped and cut his forearm. The cut was about two inches long, but not deeper than

the skin. Witness immediately disinfected with neat turpinal the wound which in itself was not serious, though it would be serious if it was infected with glanders. He washed the arm with a solution of turpinal, rubbed some in, and then bandaged it up. The examination had been practically completed at that time. Witness heard a week later that the deceased was poorly, and was told that he had been to a doctor, who said he had blood-poisoning. The deceased's brother told him then that he was rather better. The previous Friday hearing that the deceased was seriously ill, he went to the house, and was told that his condition was serious. Glanders was very serious, but witness did not think there was any danger after what he had done in disinfecting the wound so carefully and promptly.

By the Jury: It was not necessary to hold a post-mortem examination on every horse that died from glanders, but he had instructions from the Kent County Council to make one on all horses which were supposed to have died from glanders. The deceased clearly understood that there was danger, but witness did not consider it necessary to tell him to go to a doctor. He had never had a case of that kind before.

Allen Hoare, Inspector under the Diseases of Animals Act, appointed by the Kent County Council, and living at 7 Methuen Road, deposed that on Saturday, July 29, he had a report of an outbreak of glanders at the Oxford Mews, Bexley. Witness called in the veterinary surgeon, who gave a certificate that it was glanders. On Sunday, July 30th, witness saw Mr. McGill, and asked if his son could slaughter a horse the following day. He meant his son Fred, whom he had been used to having, but Mr. McGill said he could not go, and Herbert would go. On Monday, July 31st, the Divisional Committee at Dartford made an order for slaughter, and the time was fixed, but in the meantime the animal died. Deceased took the carcass to the railway allotments at the back of the mews, where the pit was ready to receive it. After the arrival of the veterinary surgeon, the deceased opened the horse, and, in taking out the windpipe the knife slipped. Mr. Robards dressed the wound very quickly. The deceased did not seem very frightened about it. The horse had been suffering from glanders. The deceased helped to roll the body into the pit. Witness heard the next day that deceased felt queer, but did not think it was serious after what Mr. Robards did in dressing his arm. He understood that the deceased told the doctor the wound had been disinfected for glanders. Witness reported the outbreak of glanders to the Medical Officer of Health (Dr. Sunderland), but did not mention that the deceased had cut himself.

Dr. J. Leith Leslie, of the Broadway, Bexley Heath, said the deceased came to him on the morning of August 3rd. He complained of a cut on his left forearm, which was about 1½ inches long, gaping, but not deep. It looked very unhealthy, and the lad explained how the wound occurred, and that Mr. Robards had cleaned it up and bandaged it, so that he did not think it was necessary to go to a doctor. At that time the deceased did not say that the horse he had been cutting was suffering from glanders. On August 8th the deceased showed symptoms of general blood poisoning, and later developed symptoms typical of acute glanders. He died on the 21st from exhaustion from acute glanders. Nothing more could have been done for the deceased so far as witness was aware. The treatment for glanders, which should be carried out at once, was to excise the wounded part and apply very strong disinfectant. It must be done immediately. He did not know the disinfectant Mr. Robards used. When witness saw deceased nothing more could have been done for him beyond what was done. About 90% of the human cases of glanders ended fatally. Witness had never seen a case before.

In reply to a jurymen, Mr. Robards said that the dis-

infectant he used was generally employed in a 2½% solution, but he applied it in this instance in 8%. The deceased complained that it burnt him, showing that it had taken action, and was strong. He did not think that it could be said that the disinfectant was not effective. Some microbe must have got to the blood very rapidly.

The Coroner, in summing up, said the cause of death was perfectly clear, the deceased becoming infected with glanders while helping to perform a post-mortem examination on a horse that had died from that disease. They had heard that disinfectants were applied immediately, but apparently the blood stream became infected very quickly, and before the disinfectant had time to work. He then proceeded to give his experience in a couple of cases of tetanus, and observed that it was quite easy for the blood to become infected. He thought the proper verdict would be "Death from misadventure."

A Jurymen: Do you think if he had seen a doctor sooner it would have been any benefit to amputate the arm?

The Coroner: It would be a dreadful thing to cut a man's arm off whether infected or not. A doctor could not say for a few days whether it was infected.

In reply to another Jurymen, Mr. Robards said that gloves were not worn by deceased or by witness. Some wore them, and some did not for these cases. In this instance it was not the hand but the arm that was cut. He usually looked at the hands of the one helping him to see whether there were any cuts.

The Coroner: I have no doubt that after this the veterinary surgeon will take care to see that the man helping him is protected.

Mr. Robards: Certainly, I will see that the man is provided with gloves.

The jury returned a verdict of "Death from misadventure," and passed a vote of condolence with Mr. McGill in the loss of his son. — *The Express* (Kent).

PARLIAMENTARY.

SCOTTISH LAND BILL:

NEW AGRICULTURAL DEPARTMENT.

In the House of Commons, on Monday, Nov. 6.

On the report stage of the Small Landholders (Scotland) Bill.

Mr. C. BATHURST (U.) moved that the Bill be recommended to a Committee of the whole House in respect to Clause 4. When the Bill was committed to the Standing Committee on Scottish Bills, it contained a reference to Commissions who were to have certain powers. As it came back, a separate Board of Agriculture for Scotland was mentioned for the first time. Since it had become known to English agriculturists that the Board of Agriculture was no longer to have the entire administration of the Diseases of Animals Act throughout Great Britain, every meeting of agricultural associations in England which had been held had passed a unanimous vote asking Parliament to refuse to allow this clause to pass into law. During the past month, also, the Scottish Chamber of Agriculture had passed a resolution of protest by a majority of two to one.

Sir T. C. WARNER (R.) seconded. Even if Scotland had the management of her own affairs, he thought it would be wise on her part to have a central body for the whole of Great Britain to make regulations with regard to diseases of animals. (Hear, hear.)

Mr. COURTHOPE (Sussex, Rye, Opp.) thought the right hon. gentleman had rather misunderstood the point of the argument. The whole argument was based on the ground that diseases of animals affected British rather than merely Scottish interests, and that the administra-

tion of this important matter should be under one Department and not two. It was a matter of common knowledge that the advantages which Great Britain enjoyed of being able to send pedigree stock to foreign countries rested on the great rigidity and strictness of administration as regards disease. It was also known that countries like the United States and the Argentine knew no boundaries whatever except the sea. If there was any laxity of administration on this question in Scotland—and the opinion prevailing among a large section of Scottish agriculturists he thought warranted such a fear—the whole of Great Britain would at once lose the advantages she possessed in that direction. If there was a division of administration between the two countries the risk would be great before the new Scottish Department got into harness, and the English Board would have to treat Scotland exactly as it treated foreign countries in relation to the movement of animals. There would have to be the same kind of restriction, and, while that would be a very undesirable thing for England, it would be disastrous to Scottish agriculture.

Mr. URE said the Government would support the Bill. Its main purpose was to set up a Scottish Board of Agriculture, and he could not see what harm would thereby be done to the English farmer. If he were asked to state which was the most important of the powers of the new Board, he would say the administration of the Contagious Diseases of Animals Act.

Mr. LONG declined to look at the matter as a purely Scottish question. The Government, in setting up a Scottish Board of Agriculture, were going to confer on the Scottish Secretary the unchallenged right to take from the present Board of Agriculture for England and Wales whatever powers he thought fit to demand. The Secretary for Scotland was to have the absolute right to make such regulations as he chose for the control of the new Board. They had no right to make this unheard of change in a bill, which did not settle the matter by definite and statutory provisions, but which gave powers to one Minister at the expense of another. (Opposition cheers). During the last forty years enormous progress had been made in the work of stamping-out disease in Great Britain, and it was of the greatest importance to have one man at the head of affairs, who could form an opinion, and then promptly act upon it. (Hear, hear). This proposed change would be a fatal mistake. It would expose to great risks cattle to the value of many millions of pounds, and would arouse in the minds of agriculturists the gravest possible anxiety. (Opposition cheers).

Mr. BECK (R.) said he discovered to his sorrow and surprise that this so-called purely Scottish Bill put English agriculture in grave peril. (Hear, hear). Those who sat for rural constituencies were bound to fight this proposal tooth and nail. (Cheers).

Mr. CHAPLIN (U.) said that one danger to this country by this proposal was that the Continent was reeking with foot-and-mouth disease, and it became more and more difficult to protect this country. Absolute unanimity of treatment guided by one mind was essential for success.

Sir W. MENZIES (R.) said that surely it was not beyond the ingenuity of those who objected to this clause to frame an amendment so that, as regarded the contagious diseases of animals, there should be uniformity.

Mr. HICKS BEACH (Gloucester, Tewkesbury, Opp.) suggested that those Scottish members who had spoken against the motion were adopting tactics which were unlikely to secure the passing of the Bill. They must recognise that a strong feeling existed in England against a separate Board of Agriculture being established in Scotland, and that in Scotland also there was a strong feeling against having a separate body to

administer the Diseases of Animals Acts. The administration of those Acts should be under the control of one authority for the whole of Great Britain; whether that authority had its headquarters in Scotland or in England he did not care. However many Boards of Agriculture might be set up in Great Britain, Ireland and foreign countries which imported cattle would continue to treat Great Britain as one country, and a separate administration would be of no advantage to Scottish agriculturists. He regretted that the recently appointed President of the Board of Agriculture was not in his place during this debate. (Hear, hear.)

On a division, the motion to recommit the Bill was defeated by 197 votes to 113—majority 84.

Mr. H. HOPE (U.) moved an amendment to substitute a Scottish Department of the Board of Agriculture and Fisheries for the "Board of Agriculture for Scotland" which it was proposed to establish.

Mr. URE said the Government could not accept the amendment. Scottish members were fully alive to the efficiency of the Board of Agriculture and Fisheries, but they believed they had in Scotland material for establishing an equally efficient board for the control of Scottish agriculture.

Mr. LONG said the only security the British farmer now had against disease was the vigilance of the Board of Agriculture, and now, for sentimental reasons, the powers of that Board were going to be impaired. The Bill would strike a blow at agricultural prosperity, of which its authors would live to be ashamed. (Cheers.)

On a division the amendment was rejected by 130 to 74.—*Daily Telegraph*.

Acorns as Food for Stock.

Mr. John Hughes, an agricultural analyst of much experience, is strongly in favour of their use. Some years ago he made a study of the question, and the results of his investigations are embodied in a pamphlet.

Acorns in moderation are, he says, a wholesome and suitable food, and because animals have died from a too greedy consumption of a certain food itself is to blame. He quotes Sir George Jenkinson, of Eastwood Park, Gloucestershire, whose long experience enabled him to say that ripe acorns are good for cattle, the danger being when young stock on short keep get access to the unripe fruit.

From the results of analyses made by Mr. Hughes, it is seen that of every 100lb. of acorns 86.29 consists of a very nutritious, easily digested food, and only 13.80lb. of indigestible husk.

The reason why acorns have not so far been used as food in the form of meal is probably because farmers usually have no convenient means of drying and subsequently grinding them into meal. Stored in thin layers on shelves in a large, dry, well aerated room, they would dry naturally. But for commercial purposes the drying would have to be by artificial means, in the same way that hops are treated. He found that by drying the crushed kernels at a temperature of 212deg. F., not only was the material concentrated by the expulsion of the water, but the process increased the sugar compounds and eliminated the astringent principle due to the tannin, improving the flavour in a marked degree by imparting a sweet, aromatic, biscuit-like taste.

In a table he shows that acorn meal contains more oil than barley meal, but less than oatmeal. In albuminoids it is inferior to both, but as regards digestibility it contains only 3.77 indigestible fibre, as compared with 5.14 in barley meal, and 11.01 in oatmeal. He calculates that it would require two tons of acorns to make one ton of the meal, and being a partially cooked food the meal will keep for a considerable time without undergoing deterioration. Mr. Hughes points out that acorns lying

about in the fields remain a source of danger to cattle and horses, and hundreds of tons of good, nourishing, and palatable food are annually wasted.

Mr. Carrington Smith writes from Admaston, Rutley:—During more than half-a-century's occupation of a farm, upon the grazing land of which there have been growing many acorn-bearing oaks, I have not had a single instance of loss, although both cattle and sheep had free access to heavy falls of acorns for weeks together. In 1858 I bought about 100 bushels of acorns gathered by women and children, by leave of the landowner, in copses and in fields occupied by tenants. These acorns, for which I paid about a shilling a bushel, were poured down in a heap on the wooden floor of an old barn, and were both a valuable and safe food for all live stock during the following winter. Slight fermentation and sprouting mellowed the heap. In 1868 the acorn harvest was of splendidly large fruit, perfectly ripened and free from their cups and twigs. During a later period of this so-called autumn acorns have been lashed off by wind with cups and twigs attached to them. My complete immunity from any loss from 1856 onward may fairly be attributed to the fact that whenever outside grazing falls off I feed freely both home-grown fodder and bought food.

Seventy cattle belonging to Mr. J. Bishop, of Haughton, Shifnal, have died from eating acorns. The cattle were grazing in a field in Aqualate Park, Newport, Salop, belonging to Sir William Boughey, where the acorns were exceedingly plentiful. The loss to Mr. Bishop is estimated roughly at nearly one thousand pounds.—*Farm and Home*.

The Traffic in Old Horses.

Sir Cecil Hertslet, British Consul-General in Belgium, reporting on the trade and commerce of that country, in alluding to the traffic in horses between England and Antwerp, says:

"I can emphatically state, upon the best authority, that horses now permitted to be embarked in the United Kingdom are, without exception, in a fit state to undergo the voyage to Antwerp without cruelty.

"The work of the veterinary inspectors appointed at various ports in the United Kingdom is carried on in a thoroughly conscientious manner.

"Short of absolute prohibition of the trade in old horses, it seems impossible to deal more strenuously with the matter in the United Kingdom, and in common fairness it would be unjustifiable, to remove from the British dealer the market for old horses now existing in England."—*Eastern Morning News*.

Macadam and falling Horses.

Mr. John McBeth, writing to *The Scotsman*, says:—

"When driving home this week I observed a very good and capable horse being assisted after falling on the brae opposite Lugton, Dalkeith. The marks on the tarmacadam clearly showed the cause of the downfall. Part of this brae has been made little else than a skating rink for horses. This is anything but a solitary case on our suburban roadways. Others who have narrowly escaped or have suffered when driving can testify to the extremely dangerous stage in which some of our roadways are. There is surely a medium between keeping down the dust and practically driving horses off the road altogether. It was once suggested to make special roads for motor traffic. The idea was scouted, but they are now being made at the expense of the other road traffic. So when a horse falls and damage results from a road made unsafe and a veritable trap, should not the Road Authority pay the damage and restore the roadway to a state of safety at once."

Addresses Wanted.

The following names will be removed from the Register R.C.V.S., 1912, failing information as to the present addresses of the members.

Name.	Last address known.
Bayes, James, late of Agricultural Department,	Cape Town, S. Africa.
Bird, Robert H.,	Fort Collins, Colorado.
Brassington, A., 15 Mornington Rd., New Cross Rd., S.E.	
Casewell, W. Thos.,	Newport, Salop.
Cobbedick, J. O.,	Queen's Row, Clifton, Bristol.
Davies, Arthur W.,	Lennox Taylor Co., Iowa, U.S.A.
Deakin, Herbert Walmsley	109 Welbeck Street,
	Ashton-under-Lyne, Lancs.
Dowell, Frank W.,	128 Jermy Street, St. James', s.w.
Farrell, Capt. G. H.,	Hyderabad (Deccan), India.
Featherstonhaugh, H. H.,	King's Somborne,
	Stockbridge, Hants.
Hall, James W.,	40 High Street, Hawick.
Jackson, A. F. S.,	Johannesburg Turf Club,
	Johannesburg, S. Africa.
Kennedy, W. R.,	216 Selhurst Road, South Norwood, S.E.
MacLaren, John H.,	Sweethope, Shawhill Road,
	Shawlands, Glasgow.
Muirhead, John T.,	14 Merchiston Gardens, Edinburgh
Scott, William,	Royal Artillery, Victoria Barracks,
	Sydney, N.S.W.
Simpkin, F. A.,	Grosvenor House, Horncliffe Road,
	Blackpool.
Smith, Steven Marsh,	late Capt. A.V.C.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*,

WAR OFFICE, WHITEHALL, NOV. 3.

TERRITORIAL FORCE. ARMY VETERINARY CORPS.

C. R. Chadwick to be Lieut. Dated Oct. 10.

Nov. 7.

REGULAR FORCES. ARMY VETERINARY CORPS.

Lieut. L. L. Dixon, from the Half-pay List, is re-stated to the establishment, with precedence next below A. S. Lawrie. Dated Nov. 8.

It is with regret we have to announce the death of Capt. B. H. Lane which occurred on Nov. 5th, at Meerut, India, from concussion of the brain. This officer graduated on July 13th, 1904, commissioned Lieutenant, Army Veterinary Corps, 4th Feb., 1905, promoted Captain, 4th Feb., 1910.

Nov. 8.

Capt. E. P. Argyle has been transferred from Aldershot to Netheravon to take up the duties of Veterinary Officer to the Cavalry School, replacing Capt. J. J. B. Tapley who has been selected for appointment to the Egyptian Army.

The undermentioned officers arrived from India in Transport "Rewa" on 1st November, and have been posted to the Aldershot Command: Major A. England, Capt. P. V. Beatty, H. M. Williams.

INDIA OFFICE, NOV. 3.

APPOINTMENTS TO THE STAFF.

The following appointments have been made to the Staff have been made in India:

ARMY HEADQUARTERS STAFF.

QUARTERMASTER-GENERAL'S BRANCH.

To be Assistant Principal Veterinary Officer in India. —Capt. M. St. G. Glasse, Army Veterinary Corps. Dated Oct. 1.

To be Inspecting Veterinary Officers.—Col. F. W. Forsdyke, Army Veterinary Staff, Lieut.-Col. E. Taylor, Brev.-Col. E. R. C. Taylor, Army Veterinary Corps. Dated Oct. 1.

CORRESPONDENCE.

GASTRIC AFFECTIONS OF RUMINANTS.

Sir,

I have read with much interest the various letters with regard to the gastric affections of ruminants. I quite agree with Mr. Nash in his remark that it is wonderful how many persons give such large quantities of salts, treacle, linseed oil, etc. without killing the cattle to which they are administered. Salts are a medicine I have not given to cattle for the last three years, and from my experience during this period I have determined not to return to a remedy so drastic in its effects. Large quantities of salts, when given to cattle, enter the rumen and mix with its contents. The taste of the salts is disagreeable to animals, and consequently they refuse to chew the cud, and the bolus is returned to the rumen without being masticated. I have seen cattle remain in this condition for a long time.

The method I now adopt is to give a seven, eight, or nine dram. ball of aloes (encapsulated), which at once passes into the omasum. My experience is that the chewing of the cud is not interfered with, and this, in my opinion, is of great importance. When cattle are given aloes they do not scour violently, nor do the animals sicken. I have frequently seen cattle after receiving a capsuled ball begin to chew the cud immediately afterwards, and continue to do so as if nothing unusual had happened. That is a most satisfactory condition in which to find one's patient. Another reason why I continue to give those capsuled balls is that the bowels respond much quicker, and the action is neither so violent nor so drastic as that of salts.

When giving balls to cattle I used invariably to injure my hand on the sharp edges of the molar teeth. In fact I found it almost impossible to avoid injury even should I use the balling iron or mouth gag, as cattle have much more lateral movement of the jaw than the horse. I therefore had to find some method to protect my hand, and after many experiments I devised a balling gun which effectively prevents injury either to the operator or to the patient. To those desiring information regarding the instrument I shall be very pleased to forward particulars.

There is frequently a distention of the rumen with gas. When the rumen becomes extensively distended I am of opinion that the stomach becomes paralysed. Previously in cases of this nature I frequently used the trochar and canula, but latterly I have used the probang only. I withdraw the stielate, and thus allow the gas to escape, and this, in my opinion, is greatly superior to the use of either trochar or canula. After the gas has been allowed to escape I usually give an eight or nine dram. ball of aloes followed by amm. carb. in 1 oz. doses.—Yours etc.,

JOHN M. STEWART, M.R.C.V.S.

COST OF MOTORING FOR A V.S.

Sir,

It was with a feeling of trepidation and fear that I penned the few lines on the above in your issue of the 28th ult., wondering if the columns of your estimable journal (although I felt the matter would interest many of your readers) would be open to such a subject. Hence I felt I must be brief. I gladly accede to the request of Mr. Begg, and give below some further particulars. The 8 h.p. Renault was new when purchased, the price of £205 being for the car with two-seated body. The fittings, all of which I consider absolutely necessary for any comfort, cost £35 (not £38 as appeared in the issue of the 26th ult.), and thrown in with this amount I had the services of a man for six days to learn me to drive the car. The details are as follows:—

Hood with side curtains	£8 0 0
Glass screen and fittings	5 0 0
Two side lamps	2 0 0
Tail lamp	1 0 0
Head light	4 0 0
Stepney wheel with tyre, waterproof cover	7 7 6
Horn	1 5 0
Side doors	3 3 0
Lifting jack	15 0
Registration fee	1 0 0
Number plates	7 6
Head light bracket	1 5 0

Total £35 3 0

I drive the car myself, and purposely omitted the cost of the man's wages because the idea in giving the short summary was to contrast the cost with that of keeping horses, and most veterinary surgeons keep a groom of some kind or other. The man's wages are 19/- with cottage which I could easily let at 5/- per week, total 24/-, and although much of his time is occupied in gardening, I have thought perhaps in arriving at the cost of keeping a car it is best to debit the whole of his wages to that object.

The depreciation and tyres are the two most important items to consider in estimating the cost of keeping a car, and obviously I cannot yet speak authoritatively as to the former. But I think if we say the car will last five years before it is either obsolete or done, that will not be far out, although I have known one car of this make which ran for 60,000 miles. The depreciation will therefore figure at £48 per annum. Each year after the first a certain sum will be incurred for painting, renewals of bearing, and general repairs. For this £10 will probably be a conservative estimate, notwithstanding the fact that this make of car is one which wears well. We may condense the items in the following manner:

Running expenses	per annum	£50 19 9
Wages	...	62 8 0
Depreciation	...	48 0 0
Repairs	...	10 0 0
		£171 7 9

Per mile on an estimated mileage of 6,5750:

Running expenses	... 1 s. 1 d.
Wages nearly	... 2 22
Depreciation	... 1 70
Painting and repairs	... 35
	6 08

I think this district with its proximity to the flint bearing strata of the Southdowns, which flints are used for repairing the roads, is rather hard on the tyres.—Yours faithfully,

HENRY TAYLOR.

Hayward's Heath.

Sir,

I bought a 6 h.p. Rover car, new, and ran it for two years. I kept a special file for the bills. I sold it for £40 at the finish. Including depreciation in value it cost me £3 per week all the time I had it. I am now using a 7 to 9 h.p. Swift, which does quite 10 miles more to a gallon of petrol, and as yet requires very little repairs.—Yours faithfully,

J. H. PARKER, M.R.C.V.S.

Faringdon.

Sir,

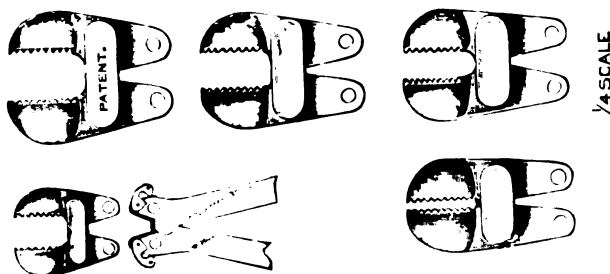

I am now in my fourth year of motoring and find the cost works out about as follows: Maintenance, that is petrol, oil, grease, tyres, and repairs of all kinds £100 a year. depreciation £50 a year, man £50. I have covered from 10,000 to 12,000 each year, and used first a six horse power Rover, and latterly a 8 h.p. Rover, both of which I bought new.—I am, your truly,

E. D. JOHNSON.

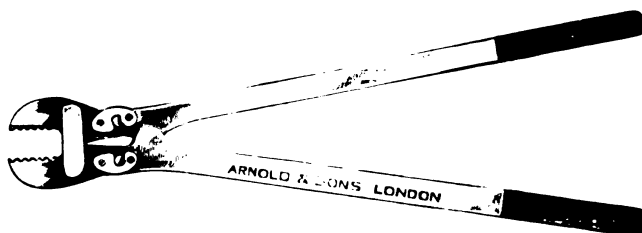

Nottingham.

PRACTICES FOR DISPOSAL

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

HOME COUNTY. Receipts £350 to £400 per ann. Rent £35. Premium required £200.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SCOTLAND. Returning over £300 per annum. Expenses very low. Premium £120, or nearest offer.

YORKSHIRE. Receipts 1910 £332. Rent £19. Premium £300.

No. 1219.

NOVEMBER 18, 1911.

Vol. XXIV.

NITROUS OXIDE IN CANINE PRACTICE.

This week we print an article which may ultimately introduce a new method of inducing anaesthesia in every-day canine practice; and the joint authors—a dentist and a veterinary surgeon—form an ideal combination of workers upon this particular question. Hitherto nitrous oxide gas has been practically, if not absolutely, unused in veterinary surgery; and these experiments therefore mark a new departure. Eventually, it is very possible that it may come to fill a distinct place of its own in minor surgery upon the dog, at least.

Observations upon three subjects, even though repeated, do not justify final conclusions. So far as they go, however, the experiments undoubtedly all point in one direction. They indicate that dogs may be quickly, easily, and safely anaesthetised by nitrous oxide gas; that the period of anaesthesia in them lasts about as long as that in human beings; and that recovery is much more rapid than is the case when chloroform is used—the latter being a great advantage in practice. It is certain that the drug deserves an extensive clinical trial. Of course its use in veterinary surgery, as in human practice, will always be subject to considerable limitations; and experience, with perhaps further modifications of apparatus, are required to precisely determine these.

On the whole, the record of our profession in this country with regard to anaesthetics is not by any means a full one. We have certainly no cause for self-reproach as regards cocaine and the various more recently introduced substitutes for it. But it will always be a blot upon our history that, though a few of us have used chloroform practically ever since it was first introduced, its popularisation amongst us has only taken place within the last twenty years. Probably even at the present day, some of us might advantageously study the whole subject of anaesthesia by inhalation more closely; and those who do will find it worth while to examine the ideas and technical methods of medical men and dentists. The most recent human text books may be consulted, and the most modern human apparatus studied—not for blind imitation, but for careful and intelligent adaptation to our own purposes. The whole subject has undergone a great deal of development within the last few years in the medical profession; and we should be unwise to ignore its results.

BILATERAL PURULENT NEPHRITIS: A SEQUEL OF "REDWATER."

The subject of this short contribution was a six-year-old shorthorn cow, in her third pregnancy. This animal, for a period of twelve months, had shown from time to time violent internal pain, as if from colic. In October last she had an attack of "redwater."

The breaking down of blood constituents was apparently much relieved by the exhibition of dilute acids, and the constipation was effectively overcome by mild purgative drenches, followed by Ol. lini., stimulant and tonic powders, composed of Pulv. rad. cinchona, Nux vomica, Ammon. carb., and Zingiber.

After an improvement lasting for four or five days the patient began to show signs of a relapse; the urine again became of a weak port wine colour; the pulse was very rapid, total anorexia was present, dullness, and lassitude were shown, as a result no doubt of septicæmia, and life was only maintained by frequent dosing with gruel and the medicines mentioned above. At intervals of a few minutes, the cow would moan piteously and grind her teeth; she also used to stand with her hind legs crossed, and her back bent downwards, and very taut, and manipulation in the region of the kidneys was painful. About this time the passage, per urethra, of purulent material began, and I was convinced that the case was hopeless. The faeces and urine were very mal-odorous. The patient died in a deep coma about three days after the last mentioned symptoms made their appearance.

On post-mortem examination every organ but the kidneys and uterus was healthy. The uterus showed very recent tuberculosis on its peritoneal surface. The kidneys gave evidence of chronic nephritis, being fibrous, with a firmly adherent capsule. On transverse section it was seen that the cortex of the kidneys was mostly broken down into a deep red, foul smelling, grumous material.

I record this case principally to invite descriptions of similar ones from your readers, and to learn if there are any symptoms other than the passage of discoloured mal-odorous urine, which can be considered *typical* of nephritis, whether simple or purulent.

It is worthy of note that the temperature remained normal until the beginning of apparent dissolution when, of course, there was a marked and rapid decline.

L. L. STEELE.

Beckermert.

ADMINISTRATION OF NITROUS OXIDE GAS TO DOGS.

By H. HARLING CAPES, L.D.S., EDIN., Dudley;
and R. LEWIS GREEN, Capt. A.V.C.(T.), Dudley.

Date: 22nd July, 1909, 7.30 p.m., cold night.

Case I: Subject.—Wire-haired terrier bitch. Gas administered for two and a half minutes, and she was not under. The face piece was then removed and grease put round the edge of it, when she became completely cyanosed and well under the influence of N_{20} in one and quarter minutes. Estimated she took six gallons of gas. Recovered when face piece was removed and allowed plenty of air.

Case 2; Subject.—Black and tan terrier bitch (mongrel). Became completely cyanosed in two minutes, five seconds. She had rigors twice, which did not occur in Case 1, but was noticed in Case 3. Respirations ceased and she lay collapsed for some time. Estimated took six gallons. Recovered when face piece was removed and allowed plenty of air.

Case 3: Subject.—Fox terrier bitch in whelp (condition poor). She took two gallons in fifty seconds, when outlet valve became defective. The face piece was removed and the valve readjusted, then we gave her about another four gallons, making six gallons in all "without air" when she became completely cyanosed. She was totally collapsed and had rigors twice, her heart was beating, but respirations practically ceased for almost thirty seconds.

We forced the last four gallons to see if it would kill her. The face piece was then removed, she breathed once of her own accord and then artificial respiration was resorted to, when she took five minutes to recover and was then able to stand. Violent twitchings of the head and ears took place on the ears being "flicked" or pinched.

These animals were fed at 10 a.m., and they took the gas quietly with almost imperceptible struggling. Two of the animals took no notice of a pin being stuck into the ribs or tail; showing that they were sufficiently under the anæsthetic to enable any small operation to be performed. Pupil dilated, conjunctival reflex gone.

"Repetition" on same three dogs in same order, 27th July, 1909.

Case I.—Four gallons was given first administration, she was one minute going under and cyanosed. Administered again immediately, five gallons in 45 seconds, and was completely under, cyanosed and rigors. Air was administered each time.

Case II.—"Given with air." First administration four gallons, was completely cyanosed in one minute forty seconds. Rigors. Was under the influence of N_{20} about thirty seconds (the same as is usual in the case of a human being).

Second administration "without air." Nine gallons, and she was completely cyanosed in one minute thirty-five seconds. Breathing ceased, and she was dead in one minute thirty-six seconds.

Case III.—Gave four gallons in $1\frac{1}{2}$ minutes, very little cyanosis, eyes insensitive. A very small amount of air was given and she was under about thirty seconds.

Second administration. Gave four gallons and she was completely under in one minute but only slightly cyanosed. She had slight rigors during recovery.

This bitch was pregnant and the whelps were alive.

Muzzle.—The muzzle was specially made, and can best be described as a very "elongated face piece" the same as used by dentists, with a vertical expiratory valve. The gas was admitted through a two-way stop valve exactly similar to the one used by dentists. The one way admits N_{20} only, the other admits air only and shuts off the N_{20} . The skilful administration of a little air with the N_{20} prolongs the period of anæsthesia. It is very evident after these experiments, that, in the hands of a competent anæsthetist, it is quite easy and perfectly safe to administer N_{20} to dogs, and they remain under the influence of the gas a sufficient length of time to enable one to extract one or two teeth, or perform any minor operation which only takes a short period.

We were both very surprised at the amount of gas these animals took, and on the second date, viz., 27th, we were endeavouring to kill them, but found it more difficult than we anticipated.

Another very great factor in favour of N_{20} is the short space of time they take to recover. This is totally different to $CHCl_3$.

Signs of Anæsthesia.—The general signs of anæsthesia in dogs are very much the same as in the human being, viz., a good pulse, full, firm, and slightly quickened. Relaxed muscles usually, but sometimes rigidity occurs. No stertor or jactitation was noticed in the dogs.

Cyanosis.—Cyanosis in dogs is specially noticed on the lips and tongue, and in our opinion this cyanosis coupled with muscular relaxation is the surest guide as to when to remove the face piece. Absence of "conjunctival reflex," in our opinion, is of no value as a guide in the case of dogs.

We believe that with practice, and an improved apparatus, it would be quite possible to give "prolonged gas to dogs."

Animals placed in "irrespirable gases" become convulsed before death, but when made to respire N_{20} , their respiration simply grows more and more shallow, finally ceases, and the animals die painlessly.

Touchstone's skeleton is carefully kept in a state of immaculate preservation at the Eaton Stud, near Chester. Touchstone's skeleton is doubly interesting from the fact that the horse is seen to have possessed nineteen pairs of ribs, which is one more than Nature ordinarily allows the equine race. Arranged below Touchstone's remains are the shank bones of the famous mare Beeswing, and her union with Touchstone resulted in Newminster. Buried close by these bones are three peerless mares—Shotover, Angelica and Lily Agnes.

ABDOMINAL WOUND WITH PROTRUSION OF INTESTINE IN THE CAT.

A female cat, aged about two years, was sent to the Infirmary for treatment on August 3rd, with the history that she had fallen on to a greenhouse roof and sustained a serious wound.

The animal arrived in a small basket, having been sent a journey of two miles. On examination a large amount of intestine was found protruding from a wound in the abdominal region, in front of the umbilical region and a little to the left of the median line. The wound easily admitted three fingers, and was of a jagged character. Another wound was found on the flank, which, however, did not extend through the abdominal muscles. The intestine and omentum were soiled by earth and by portions of wood fibre bedding, and were commencing to get dry. After administering chloroform I removed all the torn and soiled omentum, cleansed the intestine with a weak solution of Liq. cresolis, then washed with solution of Peroxide of hydrogen, replaced the intestine, cleansed wound as far as possible, sutured first the muscular wound and then the skin with Japanese silk, applied a large compress of double cyanide gauze soaked in Peroxide of hydrogen, then a layer of cotton wool and bandage. The diet was restricted to milk, which the animal took of her own accord.

On August 6th, as there was no action of the bowels, $\frac{1}{4}$ grain of calomel was given; and on the 7th two doses each 1-10 grain were administered at an interval of three hours, also an enema. The bowels acted at 4 p.m. On the night of the 7th the animal tore off the dressings and licked the wound, but fortunately did not injure the part or disturb the sutures. The second wound, however, supplicated and was slow in healing.

On the 8th small amounts of bread well soaked was allowed in the milk. The important wound healed well, but in consequence of the animal's tendency to lick the second wound the dressings were not left off until August 29th. She was sent home on August 31st, much to the surprise of the owner.

Remarks.—I report the above case, not with a view to demonstrating any surgical skill on my part, but to point out the remarkable powers of *vis medicatrix naturæ*. Indeed my technique would, by all the "high priests" of aseptic dogma, be regarded as heterodox to a marked degree. For I did not use a razor to remove the fur, neither did I boil the sutures nor the instruments.

But my excuse is that there was no time to spare for attending to the toilet of the peritoneum; the intestines were a long time exposed, and the animal was suffering from a certain amount of shock.

Why the serious wound should have done so well and the other so badly, is explained by the fact that the skin in connection with the latter was much bruised.

No doubt had I conformed to the rules of aseptic surgery, I should have attributed the result of the

case to the employment of these measures. But there was a possibility that while carrying out the necessary technique the patient might have succumbed from shock.

E. WALLIS HOARE, F.R.C.V.S.

Cork.

TUBERCULOSIS—BY INGESTION (?)

The subject of this case was a light bay gelding, aged eleven years. Nine months ago the owner noticed a small swelling, situate about the middle of the neck on the near side. No other swellings were visible, and except for an attack of influenza about five years ago, the animal was working every day and in good mettle.

My client was recommended by a friend to rub the swelling with some sort of "blistering liquid." About a week later they noticed a swelling in the pectoral region; this swelling disappeared in a few days.

On October 7th I was called in to see the swelling on the neck, and upon probing I found it was a deep-seated tumour, extending to the cervical bones. The pulse and temperature were normal, the animal was in good condition, and was eating and drinking well. The symptoms remained the same up to his death.

I injected the swelling with Fibrolysin on Friday, October 27th, and left word I would call to give another injection on Monday afternoon.

On the Monday mid-day the groom called at my house to say the horse was unable to move, and looked like falling down. When I got to the stable and tried to move the horse he was seized with violent tremors, became very stiff, and nearly fell down. Afterwards I noticed that these symptoms were produced when I raised the animal's head.

I gave a large dose of morphine and atropine, and advised my client to call in second opinion, or to have him destroyed. My client decided to wait till morning, when he rang me up to say the horse was down and could not move, and would I chloroform him to death.

Post-mortem.—I found the tumour to be tuberculous, also there were tuberculous masses in the parotid and pectoral regions. The lungs, pleura, liver, and spleen were not at all affected. There was also a tumour about the size of a pigeon's egg on the spinal cord in the space between the 1st and 2nd cervical bones, which was the cause of the spasms when I had raised the head. The bones were also affected, and the body of the dentata was cracked, but healed up.

I report the case to show how necessary it is to make microscopical examination of tumours, for the temperature and condition of this animal certainly did not point to tuberculosis.

PERCIVAL CARTER.

Collenards, West Derby.

TWO CASES FOR DIAGNOSIS.

The following case with post-mortem examination may be of interest to veterinary surgeons who have dog practice.

Subject.—Rough-haired fox-terrier, four years old, always very healthy.

History.—Refused food on morning of Nov. 3rd. I saw dog during afternoon, found him drowsy, showing pain over stomach and vomiting even cold water. All the mucous membranes yellow.

Diagnosis.—Acute jaundice, probably due to inflammation of the intestine around the bile duct.

Treatment.—Calomel, xv. grains, and Mist. pepsin co. 3i. doses every three hours. Death occurred on Nov. 5th after gradual weakening.

Post-mortem.—The intestine blackened and necrotic in patches size of a shilling. Gall bladder was found to contain only one large clot of blood. The blood clot was ante-mortem.

While recording cases the following is interesting.

Subject.—Heifer. I was called in on Oct. 22nd to find the beast grunting and showing labour pains. Examination showed abnormal foetal presentation. I proceeded to calve cow, then decided there was some disease in the stomach.

Treatment was first Ammon. carb. and Nuxvomica, then Chlorodyne, Tr zingib. As neither seemed to relieve the pain I told the owner it was about hopeless, and he was to go on giving the cow gruel and let her take her chance. The heifer had had already been purged by an old "cow doctor."

The beast died on Nov. 9th. I saw her on Nov. 6th last, and thought then the heart had become affected.

Post-mortem showed the stomachs healthy; intestine more or less inflamed; dry peritonitis; chest contained some gallons of milky-looking fluid, one lung showing tubercle that was about the same colour as fluid and very small.

Question—was the heart affected from the first sign of disease, or was the bowel the beginning of the trouble?

FRANK B. GREER.

Appleby.

AN UNUSUAL BOVINE GASTRIC DERANGEMENT.

We were requested at 11.30 p.m. to see a milch cow the property of M.O.H. The animal in question was in good condition and a heavy milker. It was ascertained on the morning of the same day she, along with two more cows, had broken into an orchard and had devoured a considerable quantity of "fallen" apples.

Symptoms. The animal moved with difficulty—suggestive of laminitis—back arched, abdomen slightly distended, muzzle dry and hot, breathing hurried; no rumen movements, the contents of which gave a doughy feel; bowels constipated. Temp. 104.3 F.; Pulse 65 per minute; appetite in abeyance, and the milk secretion stopped.

Sixty-eight hours after this cow was seen in the orchard she was sick, and discharged between 130 to 160 apples. These apples were nearly all whole, some were halved, and there were a few still more divided, and in addition a small quantity of ingested grass was present.

The whole apples when cut into gave the appearance of being partly cooked; otherwise they looked perfectly normal.

Remarks. I think several interesting deductions can be drawn from this case;

1. It speaks well for the cow's oesophageal capacity that she could devour greedily such a number of apples without choking.

2. One would have thought apples lying in the rumen 68 hours would have undergone more serious destructive changes than these did. Placed in a vessel under the same temperature and degree of moisture for the same length of time, fermentive and fungoid changes would have undoubtedly shown themselves. This rather suggests that the mucosa of the rumen and its secretions possesses anti-zymotic virtues which we practitioners are inclined to overlook, and further that they are not altogether obliterated when paralysis sets in, as was undoubtedly the case in this animal. Perhaps this anti-zymotic virtue also explains the absence of cerebral phenomena.

3. The treatment adopted was gastric and nervine stimulation. It took apparently nearly three days to rouse the rumen into activity, for one must conclude it was when this stage was reached that emesis set in.

The unique sidelights—to me at least—that this case presents, must be my only excuse for trespassing on your valuable space. The case made an uneventful recovery.

W. SCOTT.

Bridgwater.

ABSTRACTS FROM FOREIGN JOURNALS.

ASCARIS POISONING.

Dr. R. Goldschmidt, of Munich, discusses (*Münch. Medizin. Wochenschrift*) this well-known condition. Living ascarides, and still more ascarides which have been opened, give forth a peculiar, acrid, and very repugnant odour, which is somewhat weakened by preservation of the specimens in spirit, but nevertheless is still maintained. The exhalations, especially those from the fluid contents of the body cavity of the ascaris, are highly toxic to mankind. The mucous membranes are especially affected; and conjunctivitis with violent swelling and lachrymation, catarrh of the nose and throat, sneezing, coughing, loss of voice, and asthma set in. Spasmodic coughing, and asthmatic seizures regularly occurring at certain hours, are also observed; while further symptoms are nausea, vomiting, and painful swelling at the tips of the fingers.

Most men who occupy themselves with the preparation of ascarides—zoologists and so forth—

suffer more or less from ascaris poisoning. In most cases the individual susceptibility to the condition increases with continued exposure to the irritation, till even the slightest stimulation produces the symptoms. In isolated cases, however, a personal immunity seems to be present. *Ascaris megalocephala* of the horse is more toxic to human beings than *Ascaris lumbricoides* of the man and pig.

Nothing is yet certainly known of the nature of the toxic substance. Weinland has indicated free valerianic acid as an end-product of the metabolism of ascarides, and attributes the odour to this. This, however, does not explain the toxicity of the body fluids of the parasites. In conclusion, Goldschmidt points out, as being worthy of note, the striking correspondence of the symptoms of ascaris poisoning with those of hay fever.—(*Ber. Tier. Woch.*)

TRACHEAL PERCUSSION IN EQUINE PRACTICE.

Wirth describes (*Oesterreich. Monatssch. f. Tierheilk.*) the subject of tracheal percussion, which is a physical method of clinical examination introduced at the Vienna School a few years ago by Schindelka. It consists of percussing a pleximeter placed upon the trachea and auscultating the tracheal sound thus produced at the *pulmonary* surface. Two persons are necessary for this, one to percuss, and one to auscultate, the latter being the veterinary surgeon.

The normal lung, being a bad conductor of sound, permits the dispersion of the sound of tracheal percussion, which gives the impression of coming from a distance.

When the lung is hepatized, however, the auscultator hears the percussion sound very distinct, sharp, short, and directly under the ear.

When fluid is present in the thorax, the result is that the conductivity of sound is increased in comparison with the normal lung, but is weakened when compared with the thick hepatized lung. Auscultation yields a distinct short sound which, however, is not localised under the ear as in hepatization, but seems to come from a distance.

Wirth considers therefore that the special use of this method is to assist in the differential diagnosis of cases showing thoracic dullness.

Another article upon this subject appears in the same journal from the pen of J. Babor. This author has used the method upon many horses, including completely healthy ones as well as others suffering from pneumonia, pleurisy and pleuro-pneumonia.

He advises, as regards the technique, that the pleximeter should be applied completely, flatly, and firmly against the trachea. The region of the upper third of the neck is the most preferable one. The percussing strokes should not be too violent, and the pauses between them should be as nearly equal as possible. The auscultation is carried out in the usual manner, and should be extended to the normal portions of the lung in addition to the diseased ones.

Babor regards this method as yielding useful assistance in the differentiation between pneumonia and pleuro-pneumonia. It may also, in some cases,

when pulmonary "caverns" and bronchiectases sufficiently superficially situated, exist, and are already suspected on the ground of other symptoms, assist in their determination. In addition to its utility it is a simple and quickly executed procedure, its sole disadvantage being that two persons are required to carry it out.—(*Berliner Tierärztl. Wochens.*)

THE CHEMISTRY OF TRAUMATISMS.

Cadéac and Maignon, in previous researches, have already demonstrated the appearance of small quantities of sugar in the urine of animals submitted to various traumatismes, such as ligation of a limb *en masse*, crushing of the muscles with pincers, and fractures. Similar observations have been made in human beings affected with fractures and violent contusions. The sugar which is eliminated in the urine has its origin in the traumatised tissues.

Maignon has since carried out experiments *in vitro* upon organs which have been isolated and placed beyond the reach of microbes, in conditions permitting their survival. He has thus shown that all the tissues of the organism are capable of elaborating sugar like the liver, but in smaller quantities. Two causes favour this production of glucose, viz., asphyxia and crushing, and of these the second is more important than the first. Muscles taken from an animal recently killed, and crushed at some points between pincers, or subjected to strong compression, produce much more sugar than the same organs preserved intact.

In order to determine the mechanism of this favouring influence, Maignon has more recently carried out experiments upon the muscles of the dog. He has studied the effects of crushing pushed to its last extremes until trituration is obtained, and has noted the variations undergone at the same time by glycogen and glucose. He has always found a more rapid destruction of glycogen and a more marked production of glucose in trituated muscles than in muscles simply chopped.

He has also repeated the same experiments upon muscles which, immediately after death, had been washed with an artificial circulation of normal saline solution. This measure was taken to determine whether the traces of blood which remain in the muscles after bleeding play any part in the production of sugar. The results showed that the washed muscles, free from all traces of blood, nevertheless destroys its glycogen. But while, in the unwashed muscle, this destruction is always much more marked in the trituated portions than in those simply chopped, this is not the case in the washed muscle. In the latter the destruction of glycogen is not sensibly augmented by the crushing, and is sometimes even diminished. The glucose, however, is always much more abundant in the trituated than in the chopped muscles at the end of the experiment.

In chopped muscles, the destruction of glycogen is therefore the same in washed and unwashed tissues; but the results are quite different in trituated muscles, in which the destruction of

glycogen is augmented in unwashed tissues only. This proves that the action of crushing in encouraging the destruction of glycogen, which is seen in unwashed muscles, is due to the presence of traces of blood which the trituration has brought into contact with the glycogen.

These results permit of the more precise interpretation of the experiments upon living animals in which glycosuria has been observed to follow the ligation, crushing, or fracture of the limbs. The infiltration of the tissues by the blood plasma causes local glycolytic disturbances in the injured tissues; the amylolytic ferment of the blood, brought into contact with the glycogen, accelerates its transformation into sugar. In the case of a fractured bone, it is not necessary that the muscles should have been crushed in order to produce glycosuria; the fracture of the bone is sufficient, for it is always followed by hæmorrhage.

These considerations have some general pathological interest, for they explain such facts as the frequency of complications in contused wounds in which the tissues have been more or less bruised, the appearance of abscesses following simple contusions, and the development of white tumours in tuberculous patients after traumatism. They also bear upon the occasional sudden evolution of a latent infectious disease in consequence of traumatism, and upon the fact that, in animals resistant to the inoculation of infectious diseases, the disappearance of natural immunity has been noticed to follow upon traumatism. Nocard, for instance, has shown that the rabbit, which is naturally refractory to quarter-ill, contracts this disease if the muscle receiving the inoculation is struck violently. Cadéac has also noticed that the resistance of the dog to the same disease may be overcome by placing an elastic ligature upon the base of the limb which is inoculated.—*Annales de Méd Vét.*

A TRYPANOSOME OF THE SHEEP.

H. M. Woodcock has already found, in England, trypanosomes in a sheep, and he is of opinion that these trypanosomes stand in genetic relationship to the flagellate organisms *Crithidia melophagia*, which are often demonstrable in the well-known ovine parasite, the *Melophagus ovinus*. His original article upon the subject appeared in *The Quarterly Journal of Microscopical Science*, of November, 1910. Paul Behn, having heard of Woodcock's work, but without having access to his original article, has since been investigating the same subject independently at the Hygienic Institute of the Berlin Veterinary School.

Altogether Behn examined five sheep which were accessible to him at the Institute. In one only of these he found trypanosomes, but they were extremely few in number, and the general condition of the animal seemed not to be affected by their presence.

The only method by which Behn could succeed in demonstrating trypanosomes in this sheep was by examining so-called "thick drops" stained with Giemsa's stain. He regards this "thick drop" method as the simplest and most reliable means of

demonstrating the presence of trypanosomes when they are few in number, but it does not permit of their very accurate study. It certainly enables trypanosomes to be recognised as such, but does not permit exact observation of their morphological characters. In this case, however, no trypanosomes could be demonstrated by staining thinner layers of blood, or by centrifugalisation methods; and, in fact, they were so exceedingly few in number that only about one organism could be discovered in every fifth "thick drop."

So far as Behn was able to study the organism under these disadvantageous conditions, he describes it briefly as follows. The length of the trypanosome seems to range between 25 and 40 micro-millimetres, and its breadth is from 2 to 3 micro-millimetres. The macro-nucleus lies about in the middle of the body. The blepharoblast is fairly large, and lies considerably nearer to the macro-nucleus than to the tapering posterior extremity. Behn is not yet able to speak definitely of the length of the flagellum or the disposition of the undulating membrane, as both these structures can only very seldom be recognised in stained "thick drops."

The sheep in which the trypanosomes were found was the host of *Melophagus ovinus*, as were also two other of the sheep which Behn examined. Specimens of the *Melophagus ovinus*, when examined, were found to contain *Crithidia melophagia*.

Behn has already undertaken transmission experiments, by which he hopes soon to be able to give a more accurate account of the morphology of the trypanosome, and also eventually to clear up the question of its relationship to *Crithidia melophagia*. At present, he records his discovery of an ovine trypanosome as being the first observation of the kind, to his knowledge, made in Germany. Trypanosomes have also already been found in German cattle; and it is clear, therefore, that natural infection of both oxen and sheep by trypanosomes occurs in Germany. At present it seems very doubtful whether either the ovine or bovine German trypanosome has any pathogenic effect, but the further study of both species is desirable.—*Berliner Tier. Woch.*

Veterinary Degrees at Edinburgh.

The scheme of co-ordination between the University of Edinburgh and the Royal (Dick) Veterinary College, with the object of encouraging veterinary education by granting University degrees in B.Sc. and D.Sc. in veterinary science, will be submitted at an early date for the approval of the Privy Council. The candidate for the B.Sc. degree will require to have been engaged in veterinary study for not less than four academic years, and attendance at the Royal (Dick) Veterinary College is to qualify for admission to the University examinations for the degrees. It is also a provision that one year of study must be spent at the University of Edinburgh. It is proposed that the examination for the B.Sc. degree should comprise chemistry, botany, physics, zoology, anatomy, physiology, pathology, sanitary science, and veterinary hygiene. The degree of D.Sc. in veterinary science is to be open to those who have held the B.Sc. for three years, and the qualifying test is to be a thesis on original research work done by the candidate.

The Board of Management of the Royal (Dick) College have purchased a site at Summerhall, in the south-eastern part of the city, where the new headquarters of the College are to be established. Towards the estimated cost of £50,000 the Scottish Education Department has promised to contribute one-half. The other half has to be raised by the Board of Management, who have already received promises of nearly £20,000. An appeal is being made to those interested in the advancement of veterinary science to contribute the £5,500 still required.

Injury as a Causative Factor in Cancer.

Coley (*Ann. of Surg.*, April-May, 1911) attempts to disprove the view held by many practical surgeons, and recently advocated on statistical grounds by Phelps and Segond, that trauma has no influence whatever upon the development of cancer. Including under this term all forms of malignant disease, he argues that the old and popular belief of its origin in injury should be judged by the results of wide personal experience rather than by those of statistical study. Analyses are given of 970 cases of sarcoma and of 250 cases of carcinoma, all personally observed and carefully noted by Coley. In the first group a definite history of injury was made out in 225 cases, or 23 per cent. In 52 per cent. of these 225 cases the tumour developed within the first month after the time of the injury. In the series of 250 cases of carcinoma there was a history of antecedent trauma in 82, or 32·8 per cent. Of 120 cases of carcinoma of the breast included in this table, 50, or over 43 per cent., gave records of injury.

In dealing with the argument advanced by Segond, of the absence of any definite knowledge of the condition of the affected parts prior to the accident, Coley refers

to several instances in his own practice, in which the healthy condition of the seat of post-traumatic cancer had been proved immediately prior to the accident, by careful examination. The number of such instances is certainly very small, but it is held that it is quite logical to believe that in most of the other collected cases in which circumstances did not permit the fulfilment of strict scientific conditions, especially a medical examination directly prior to the injury, the trauma played the same rôle in the development of the tumour. In the final portion of his long and exhaustive paper which is continued in the May number of the *Annals of Surgery*, the author states that in his belief the evidence based upon his extensive personal experience justifies the following conclusions: (1) Local trauma of any kind, from chronic irritation to a single local contusion, is not infrequently the direct exciting cause of malignant tumours of all types. (2) That a single local injury may cause a carcinoma as well as a sarcoma, is no longer open to speculation. The cases that the author has submitted fulfil, it is held, all the conditions necessary to establish a definite causal relationship between a single trauma and the development of a cancer. (3) This relationship in no way depends upon our ability to offer a scientific explanation of it: nor does it depend upon the acceptance of any one of the various hypotheses as to the etiology of cancer. It can be equally well explained whether we accept the extrinsic or intrinsic origin of malignant tumours. (4) Medico-legal side: The medico-legal aspect of this question is as yet in a most unsettled state. While we must admit that trauma often plays an important causative rôle in the formation of malignant tumours, this relationship must be clearly and definitely established according to principles and conditions very similar to, if not quite so exacting as, those laid down by Segond, before any legal liability can be admitted. — B. M. J.

* As Diseased or Exposed to Infection

Death from Glanders.

From an obituary notice in our contemporary, *The American Veterinary Review*, we take the following:—

"Dr. James H. Kelly died at his home in New Haven, Sunday, October 1st, 1911, in his fifty-fourth year, a victim of that horrible malady, glanders, after fifteen days of suffering, during most of which time he fully realised his condition and knew there was scarcely a fighting chance for life. In fact, it is believed he diagnosed his own case, and went to the physicians, his personal friends, with the facts. But even with this knowledge they were helpless, and despite every effort that they could put forth, and all the scientific knowledge they could summon to their aid, the brave patient at last surrendered and met the end with a calm courage and confidence that will always be a sacred memory to those who were near and dear to him.

The members of the American Veterinary Medical Association who attended its meeting at New Haven in 1906 will remember Dr. Kelly as the genial, active member of the local committee who looked after the entertainment and took care of the ladies in attendance. The line of carriages drawn up before the hotel headquarters to take the ladies to the points of interest in and around the "Elm City" is a sweet memory to many members of the association of the days when the horse was still an essential in the program of entertainment at A.V.M.A. conventions.

Cancer Research.

The tenth volume of the Annual Cancer Research Report from the Middlesex Hospital shows two points very fully—the vastness of the subject, and the very small knowledge which so far has been gleaned concerning it. No one of the researches can honestly be asserted to carry us one single step nearer the solution of the cancer problem, though some of them may very possibly do so indirectly by providing the basis of assured knowledge which shall enable some future worker to progress along lines not yet thought out.—*The Hospital*.

Horse Action at Dumfries.

Proof was led in Dumfries Sheriff Court on Thursday and Friday, the 2nd and 3rd inst.—before Sheriff Campion—in a small debt action by John Pollock, farmer, Papermill farm, Langside, Glasgow, against John Berwick, farmer, Albany Bank, Dumfries, for £100, being the agreed on price for a two-year-old Clydesdale filly named "Sweet Bloom," purchased by defender from pursuer on June 20, 1911, and delivered on July 3. The defence is that the filly was returned on the day after delivery on the ground that it was alleged to be unsound, having ringbone in both fore feet.

Mr. J. M. Haining, solicitor, Dumfries, on behalf of Messrs. Milligan and Stoba, writers, Dumfries, who were instructed by Mr. John Watson, writer, Glasgow, appeared for pursuer; and Mr. John Irving (of Messrs. Primrose and Gordon), solicitor, Dumfries, conducted the defence.

THE DEFENCE.

In view of the line of the defence the evidence on that side was first heard.

John Berwick, defender, formerly of the Burn, Thornhill, said he had some experience of veterinary science. He had an experience on farms for fully 30 years. On Whitsunday last he came to reside at Albany Bank. He had been Secretary of Dalbeattie Horse Society for 15 years. He had known pursuer for some time. He had visited his farm on various occasions along with the Dalbeattie deputation looking for horses to travel the

district. In June of this year he was in want of a mare or filly for breeding purposes, and wrote to pursuer on June 17 that he wanted a Clydesdale mare or filly. Pursuer replied on June 19 stating that he had a Clydesdale mare for sale. He stated that she was thoroughly sound and correct. He mentioned also that he had two fillies. He stated nothing about them being sound. Following upon that letter, witness arranged to visit pursuer's farm at Langside. He visited the farm on June 20. Pursuer then showed witness a filly. Witness discussed the filly with pursuer, and when he said it would not suit him pursuer said he had another at grass four miles away, and if witness saw her he thought he would buy her. Pursuer guaranteed that she was sound and correct. Witness said he would not have time to go so far, as he had to catch the train at St. Enoch Station. Pursuer said that if he would go he would see that witness got back in time for the train, and witness went. The filly's name was "Sweet Bloom." Her colour was bay, with white hair through her; her two forelegs were white, and she had a white patch on the face. The sum of £120 was mentioned as the price of the filly. Witness told pursuer that the price was too big for him. Witness did not examine the filly then. They then left the field where the animals were grazing. They went to Langside station. Witness had a few minutes to wait before his train was due. When witness and pursuer got to the station platform pursuer asked witness if he was going to buy the filly. Witness said he could not face her at the price, but he would give pursuer £80 for her if he would warrant her sound and correct. Pursuer said he would take nothing of the kind, because he had refused a higher offer. As the train came in witness offered to give pursuer even money—£100. Pursuer said he would not take that sum. Just as the train was about to leave, and before witness got into the carriage, pursuer said he would take 100 guineas. Witness said he would not give this price, and as the train was moving pursuer shouted that he would give the filly at £100. The same conditions applied in this bargain as in the case of the previous animals referred to as to the filly being sound. The following day the witness wrote to pursuer on June 21 confirming his offer of £100. Witness asked pursuer in this letter to confirm the bargain in every way. He also asked for an extended pedigree of the filly. Pursuer replied on June 22, but he gave none of the information witness asked. He simply said that the filly was thoroughly sound. After further correspondence pursuer sent the guarantee on June 30. The filly arrived on Monday, July 3. Witness examined her, and found a perceptible enlargement round each fore coronet. There was a decided ring above the coronet on the near foot. It was quite hard. On the off foot the enlargement was pretty much the same, but it was not so hard and not so full in front. After examination he came to the conclusion that the filly was suffering from ringbone. After he had examined it he went over to Mr. M'Intosh, veterinary surgeon, and asked him to examine the filly. Mr. M'Intosh came over, and examined it, and gave witness a certificate saying the filly was unsound. Witness then wrote pursuer enclosing a copy of Mr. M'Intosh's certificate, and intimating that he was going to send back the filly on the following day, which he did. The next time witness saw the filly was at Messrs. Shannon's livery stables, Glasgow, on July 12. Principal Dewar and Mr. M'Intosh accompanied him. The filly was trotted out on a hard surface. She was not going square then. Witness examined her again, and found the same as he had found previously. Pursuer and witness came to terms at that time with regard to the disposal of the animal for sale. The filly was sold at Messrs. Laurie and Symington's auction mart at Lanark on August 28 for £71 to Mr. Lorimer, West Linton. The auctioneer announced in the ring that he had been

instructed to state that there had been a dispute about the condition of the filly, and that she had been returned for ringbone, but that four eminent veterinary surgeons had certified that she was thoroughly sound. The auctioneer did not mention that the filly had been condemned by a veterinary surgeon for ringbone. He saw the filly trotted out in one of the aisles of the mart. The aisle was covered with crushed gravel. Mr. MacFarlane, veterinary surgeon, examined her. The filly was hampered in her action, but not exactly lame. Previous to Mr. MacFarlane's examination witness examined the filly himself, and found it in the same state again at West Linton, and she was going decidedly lame. Mr. Lorimer there told witness that she had been blistered. She was wearing a "cradle" round her neck. The purpose of this cradle was to prevent the animal from putting her head to the part to which the blister had been applied. This suggested to witness that something was being done for the filly. Witness was perfectly sure by examination of the filly at Albany Bank that she had ringbone, and subsequent examination confirmed that opinion.

Would you use a mare of that kind for breeding purposes?—Not if I knew it.

Is ringbone hereditary?—Yes, it is supposed to be.

Would that have any effect on breeding?—Certainly, it being hereditary.

Cross-examined: Witness did not consider that Mr. Pollock's statement that the filly was thoroughly sound was a guarantee.

Do you consider that there was any attempt on the part of Mr. Pollock to evade giving a guarantee of soundness?—I was very much astonished at having to write five times before it was forthcoming.

If I tell you that this is a full guarantee of soundness will you admit that you have made a mistake in writing so often to Mr. Pollock?—Certainly not.

Witness said he did not examine the filly at Langside. Perhaps he put his hands on her to get her height. He did not use his hands on her feet or legs.

Was this filly a fine-boned or a strong-boned filly?—I would say fine-boned or good quality of bone.

Would you say fine-boned or good quality of bone?—I would say good quality, fairly strong-boned.

Does that mean strong-boned or fine-boned, which?—She was a quality filly all over.

Tell me what she was?—I think, generally speaking, a strong-boned animal would be an animal with round bones, which would be very objectionable. This filly has bones which one generally calls quality bones—broad, fine bones.

In the course of further examination witness said that the hoof heads were very prominent. She had a fairly good foot.

In the hands of careful judges do you think they would give a prize to a horse with ringbone?—Sometimes.

Witness would not be surprised if this filly had taken a prize. Regarding the treatment to the filly at West Linton, witness said that he had been told that the blister had been applied to her fore pasterns and her hoof heads. It was indicated to witness that the blisters were put on to increase the growth of hair. This was a common practice amongst Clydesdale breeders. But the blisters in this case might have been intended to serve a double purpose. The party who applied them might have thought that that they would remove the enlargement. The blisters took no effect on the filly's feet.

Re-examined: Witness said that it was at a small local show at Cathcart, held on Papermill farm, that the filly took a prize.

EXPERT EVIDENCE.

Andrew J. McIntosh, M.R.C.V.S., Dumfries, consulting inspector for the County, said that on Mr. Berwick's in-

structions he went to Albany Bank and examined the filly. It was not a general examination but a special examination. He found the two pasterns enlarged, and he considered the filly was unsound from ringbone. He gave a certificate to that effect.

The Sheriff: Is there any chance of making a mistake, or that it is anything else?—No, I have no doubt. I saw it with my own eyes, and confirmed it with handling the feet.

In further evidence witness said he found that the near foot was hard and firm. The off foot was slightly more inflamed. The ring was less complete in the off foot than in the near foot. Any man who knew his profession could easily distinguish inflammation of the coronary substance from ringbone. There was greater lameness shown in the animal's movement with inflammation than with the ringbone.

Cross-examined: Witness said it was not the case that he had unusual views in regard to ringbone. Unless animals had ringbone he did not reject them.

Would you be surprised to hear that many eminent veterinary surgeons have stated there is no ringbone in this case?—A man should not be surprised at anything, but I would be surprised at a professional man who knows his profession doing so. She had good big feet in keeping with the rest of her structure. The ringbone in this case could not have been less than two months old. It might have been more. He did not think it was usual to find ringbone on a two-year-old filly that had never worked. He would scarcely say that in the majority of cases there was lameness with ringbone. He thought there was a natural hereditary tendency in this animal to have ringbone, because she had never worked, so that it was developing rather early. There were various causes of ringbone. The filly might have sprained herself galloping in the field, or she might have had an injury. There were different cures for ringbone, such as firing and blistering, or a continuous mercury plaster was sometimes used. An absorbing plaster with continued application was the best cure in his opinion.

Were you not surprised at the price she sold for when you had condemned her for ringbone?—Well, you don't know the machinery that may be at work. (Laughter.)

John Robert Urquhart Dewar, F.R.C.V.S., 18, Drummond Place, Edinburgh, said that he visited livery stables in Glasgow in July, and examined the filly in question. He found her, in his opinion, unsound from ringbone in her fore pasterns and off fore leg. The filly went lame. The irregularity was not the same in both feet. The ringbone was worse in the near foot. Towards the inside of the off foot it was worse outside. He had no difficulty in finding the disease. He was perfectly satisfied that it was ringbone. An animal suffering from ringbone would not be desirable for breeding purposes. Nobody who knew their work would confuse ringbone with any other disease. The pasterns of the filly were not normal; they did not correspond. He gave a certificate stating that the filly was unsound from ringbone.

Cross-examined: Witness said that he could not give an indication of the depth of the deposit in the bone. He never measured into ringbone in his life. It could not be measured in a living animal.

Can you give me an indication of the depth of the deposit?—It is not three feet. (Laughter.)

Mr. Haining: There is no need for that observation. Can you give me any indication?—It must have been over one-sixteenth of an inch. He could not say it was half an inch. There was nothing abnormal or unusual otherwise about the filly. It had just the average size of feet. He was of the opinion that the ringbone was hereditary. His reason for thinking that was because the filly had never worked. It was unusual for a filly of this age that had never worked to have ringbone. Ringbone showed most when the ringbone was forming. In

stages of ringbone there might be no pain, but they were difficult to specify.

Oh, but you are a professor and should have no difficulty?—But professors have difficulties as well as lawyers.

Richard Rutherford, in practice at 26, Castle Terrace, Edinburgh, who has for 25 years acted as examiner of the Royal College, said he visited the livery stables at Langside on 14th July at the request of Mr. M'Intosh, examined the filly in question, and found it to be unsound from ringbone disease on both fore pasterns. She was lame on the right or off foreleg, where the enlargement was the larger of the two. The disease could not be mistaken for anything else by any professional man who knew his business. Any natural enlargement of the bones would have been the same all round, which was not the case here. With that disease the filly would not be suitable for breeding purposes, as on account of its being hereditary horses with ringbone were banned by all the respectable horse-breeding societies in this country and by the colonies.

Cross-examined: He was not a breeder, and it would take a breeder with large experience to say whether it was usual to find ringbone in animals so young, but as an examiner for shows he could say unreservedly that it was quite usual to find it at two or three years old. He had seen hundreds of cases of pronounced parts due to conformation, but there was nothing of the sort in this case. The ringbone should have been visible three months before he saw it.

The Sheriff: You mean by a professional eye?—Clydesdale breeders have professional eyes sufficient for most purposes. Ringbone caused lameness during the active stage when the disease was being thrown out, and in its uninterrupted progress the horse would get so lame as to have to be destroyed, and hundreds of horses were sent out of this country to the continent, because not allowed to work with it. He had never seen, but had heard of a case in which a horse was said to be condemned for ringbone of all four pasterns, but fortunately or unfortunately, it took colic and died, and the horse was found to have had nothing wrong with it. (Laughter.) That was a mistake for normal prominence, but it happened in the case of a young examiner, and not an experienced practitioner.

Andrew Spruell, F.R.C.V.S., Dundee, said he visited the livery stables on July 19th, examined the filly, and found her fore feet "lumpy" round the coronet in process of forming ringbone. He could not definitely say she was lame, but she was going "short," which was especially noticeable in turning. He did not think there could be any natural formation that could produce that lumpiness. The disease would certainly have existed on 20th June last, and the filly would be quite unsuitable for breeding, because of the hereditary nature of the disease.

Cross-examined: The extent of the deposit on the off fore leg would be about an inch, tapering off, and that would be about the point of greatest development. He could best describe it by saying if one were to take a bantam's egg, split it in two, and lay the half on the place that would give about the depth at the most prominent part, giving about half an inch. He did not think the joint was affected, but it would be as time went on. She was a very nice filly, apart from this. Until Clydesdales went to work this disease was rarely found in them.

John Baird, M.R.C.V.S., Dumfries, formerly at Thornhill, Dumfries, and Keighley, Yorkshire, said he inspected the filly at the Langside stables on 21st August, and found the same conditions as previous witnesses. When the filly was being trotted out Mr. M'Intosh shook his umbrella, and she made a jump, and came down dead lame on the off fore foot. It was an ordinary macadam

road. The symptoms could not be mistaken for naturally large articulation of the joint.

Cross-examined: He did not travel with Mr. M'Intosh to Glasgow, but met him at St. Enoch's. Mr. M'Intosh simply told him he was wanted to examine a horse, and he (witness) did not know beforehand what was supposed to be wrong. He did not think the ringbone could have been passed by any qualified V.S. He was an old student of Principal M'Call, Glasgow.

He could not miss that?—I can't say; it is not for me to say. (Laughter.)

You could not understand any professional man passing it?—Any man could do what he likes, but I would not have passed it.

Have you advised anybody in this neighbourhood to bid for it at the sale as a breeding filly?—No, I have not. I am quite positive as to that.

Duncan Macfarlane, M.R.C.V.S., Stirling, said he went by request on 28th August to Messrs. Laurie and Symington's mart at Lanark, and examined the filly, and found the pronounced symptoms of ringbone. He had her trotted out in a passage between the pens laid with soft metal, which gave her a good chance, as the concussion would not be very hard. She went quite "creeping" on both fore feet—not going free although she did not nod like a lame horse.

Cross-examined: Mr. Berwick, who wrote asking him to go to Lanark, was quite a stranger to him. He saw the filly sold, and she made £71.

Was that a price for a lame horse to make?—I did not say she was lame. It was well enough known the beast was in dispute, and as far as the price was concerned I do not think it should come much into question, as sometimes these things are got for a purpose.

But she did get rather a good price; would not that make you inclined to think some people thought the filly all right?—Some people might not see anything wrong with it. I saw one of the farmers put his hands on it and say, "I don't think there's much wrong with it," but that is nothing. (Laughter.)

Re-examined: When sold she was not run much round the ring; she was merely walked round. The fact she was in foal to a well known horse would make a big alteration in her price. He heard the auctioneer say the dispute was about ringbone, but did not hear him say that she had been passed by anyone.

Alex. Inglis M'Callum, M.R.C.V.S., Edinburgh, said he inspected the filly at the farm at West Linton on 30th September with Mr. M'Intosh, V.S., Mr. Berwick, and Mr. Storey, V.S., of East Linton. He found the ringbone distinctly visible without manipulation before handling. The filly would be quite unsuitable for breeding "because like begets like." She was a beautiful mare but for this defect. She had a cradle on her head; he was told some application had been applied to the diseased part, but saw no traces of the treatment, though he understood it had been only recently applied. He did not see that the application was necessary to increase the hair on the pasterns, as there was plenty of it and silky. She was unsound in both fore feet from the ringbone, and the right foot was hot, and at the inflammatory stage.

Cross-examined: There was nothing else to account for the lameness, and he himself tried the shoes with a hammer.

John Storey, M.R.C.V.S., East Linton, spoke to making examination on the same date as previous witness, and finding similar results.

Cross-examined: He would not like to say that the beast was going lame from inflammation.

But quite a number of witnesses have had no difficulty in saying that?—Perhaps, but I may not be so clever as some of them. (Laughter.)

But you may be more conscientious. (Laughter)?—

All I can say is she was not going dead lame, though lame.

Proof was continued on Friday.

THE PURSUER'S CASE.

John Pollock, the pursuer, said he had had experience of Clydesdales for 40 years. He had possessed in his time some of the best and most valuable Clydesdales, amongst which were Flashwood, Gallant Lea, Hiawatha, and Montrave Viceroy. He had bought them at all ages and at large prices. From his experience he could distinguish ringbone. He bought this filly when she was six months old. He knew the filly's pedigree, and there was no trace among the entries in that pedigree of ringbone or any other disease. Her predecessors had been shown for the last 50 years, and never were condemned neither on her sire's side nor the dam's side. The filly was shown at Cathcart and Eastwood show, where there was a very good show of Clydesdales. This filly was first in her class after a tie. She was carefully examined particularly, because there was a tie. The judges were well-known Clydesdale men. The filly was carefully examined by Mr. Berwick, the defender, when he came to Papermill farm. He ran his hands over her just in the proper places and way, so that witness remarked, "Ye ken a horse, my good man." Mr. Berwick put his hands on the hoofs of the filly, and had no objection to make. Witness declared that she was sound, and he considered that that was all the guarantee required. He thought Mr. Berwick's reason for writing so often for further guarantee was that he was wanting to get out of the deal. Before he sent the filly to Mr. Berwick, and as the result of the correspondence, witness took the precaution to get Prof. John R. McCall to examine the filly. He granted a certificate that she was sound. In an auction mart the statement by the auctioneer or in a catalogue that a beast "is sound" included everything. Defender had never asked him for a veterinary surgeon's certificate. Witness had had a previous offer on the day of the cattle show on June 3 by Mr. John F. Houston, veterinary surgeon, Paisley, of £100, but he did not accept it. Mr. Houston was acting for a friend. Mr. Houston examined her twice that day. Witness had also visit from Mr. David Hume, M.R.C.V.S., Haddington, who examined the filly, and said it was sound and correct. He also was acting for a client with a view to purchase.

Cross-examined: I was in court all day yesterday. I did not see Mr. Lorimer, the present owner of the filly in court. I do not know him.

Were you and your witnesses all staying at the Station Hotel last night?—Yes.

Did you discuss in presence of the other witnesses to follow you what had happened in court?—No.

Was Mr. Robb, jun., of Glasgow, who was assisting your agent yesterday, not present in the hotel with your witnesses?—He went away home last night.

Was he not present at a discussion with your other witnesses as to what happened in court?—I cannot say, for I was not present at the time.

Was the evidence of the various expert witnesses for the pursuer under discussion amongst you last night?—Oh, it was talked over.

Did you resolve what line to take up to-day in view of that evidence?—Only one line—to tell the truth.

In particular, was not the evidence of Mr. Baird, Dumfries, discussed last night in your presence and the presence of Mr. Robb?—Oh, they might all be talked over.

The Sheriff: That sort of thing is unavoidable when you have a two-days' proof.

In further cross examination witness said the filly was bred by Mr. James Dunlop, Old Hall, Fenwick, Stewar-

mother had been sold for £180. There were four fillies at Cathcart show.

Mr. Finlay Houston, veterinary surgeon, 26 St. James Street, Paisley, said that he had examined the filly twice on the day of the Cathcart show. She was absolutely sound. He offered Mr. Pollock £100 for her, but Mr. Pollock wanted £110, and he did not sell it.

Cross-examined: Witness said he had never seen the filly since. It was quite possible that there might be something wrong now. That was five months ago. She had beautiful fine bones. There was a small splint in her fore leg. There was no swelling, and she was absolutely sound.

Andrew Hume, veterinary surgeon, Haddington, said he had examined the filly on June 12, and found her absolutely sound in every respect.

John C. Johnstone, veterinary surgeon, Peebles, said he examined the filly at West Linton on September 26 for the insurance company, and found her absolutely sound. He saw her again on Oct. 14. He examined her again, and she was still sound.

Cross-examined: Mr. Lorimer had been treating the filly's hoofs. The purpose of the blistering was to increase the growth of hair.

Prof. John R. McCall, M.R.C.V.S., Glasgow, said that at Mr. Pollock's request he examined the filly on July 1. He granted a certificate to the effect that the filly was sound with the exception of a small splint on the fore leg. He did not call that unsoundness. He guaranteed the filly sound and free from all hereditary diseases so far as he could detect. He found it was very rare to see ringbone in a Clydesdale less than four years old. Ringbone gave rise to lameness in its formation. He was an authority on bone diseases. It was one of his subjects in his lectures.

Cross-examined: Is a splint unsoundness?—It is not a real or practical unsoundness.

Would a mare in splint be considered to be sound and correct in every way?—That is a legal question.

Further pressed for an opinion on the matter, witness said that there were perhaps 80 per cent. of harness horses that had splint, and yet were perfectly sound. There were some varieties of ringbone which were believed to be hereditary. A horse suffering from ringbone was usually banned in a horse-breeding society. It was not wise to breed with mares suffering from ringbone. But it depended on the variety of ringbone.

In a young animal what would you expect to be the cause of ringbone?—It might be various causes.

Is the commonest cause hereditary?—There are so few cases seen in young animals that it would be difficult to answer that question.

Witness could not recollect having examined a two-year-old suffering from ringbone. He had seen two cases in young animals of so-called ringbone, but these were caused by accidents. It was quite possible that a two-year-old animal could have ringbone.

James Weir, farmer and horse-breeder, Sanderlands, Lanark, said he had acted as a judge for Clydesdales in the United Kingdom, America, and Canada. He was at Messrs. Laurie and Symington's Auction Mart, Lanark, on August 28th, when the filly was sold. He examined the filly before the sale, and he found her sound so far as he knew. He did not find the slightest trace of ringbone. None of her forebears had had ringbone. They were all very prominent high-class horses. He advised Mr. Lorimer to use a liniment to increase the growth of hair over the hoofs, and as Mr. Lorimer was not long in the business witness prepared a liniment and sent it to Mr. Lorimer.

John Jarvie, veterinary surgeon, Carluke, said he was veterinary referee for Messrs. Laurie and Symington, Lanark. He examined the filly the day it was sold, and found it was thoroughly sound.

Andrew Robb, veterinary surgeon, 16, Ward Street, Glasgow, said he examined the filly at Langside on July 4th, and granted a certificate that the animal was sound on the following day.

Thomas Purdie, Summerville, Sanderlands, Lanark, described as a well-known dealer in Clydesdales, said he examined the filly at Messrs. Laurie and Symington's Auction Mart, and found it was sound. It got a sufficient test to show any lameness. Witness made a bid for her.

Cross-examined: He did not buy her, because it went beyond his price.

A CASE OF MISTAKEN DIAGNOSIS.

Principal James McCall, F.R.C.V.S., Glasgow, said he had been a member of the Council of the Royal College for upwards of 30 years, was lecturer in the Edinburgh College from 1857 to '59, and in 1863, founded the Glasgow Veterinary College, and had since acted as principal, and held many official appointments, including that of veterinary inspector for the Local Authority of Glasgow, among the duties under which were those of the examination of cattle and horses exported and imported. He had been a breeder of horses since 1865. He knew Mr. Pollock as a well-known breeder, and on his behalf examined the filly Sweet Bloom on 19th July of this year. He found her perfectly sound. She was quite a strong, healthy animal, with bold and prominent hoof heads, in keeping with the formation of her limbs. She has good big feet, and in his opinion these were absolutely free from disease. It was most exceptional to find ringbone or sidebones in a two-year-old Clydesdale.

Have you ever seen a case where strong prominences or pronounced joints have been mistaken by a professional man and others for ringbone?—I have. I can cite one particular case. In the first place I may say I have a difficulty in getting my students really to believe that there are two conditions that assimilate to one another very much, and that is the natural prominences of the bones and the unnatural, abnormal or diseased prominences. There was a stallion belonging to Mr. Graham, of Eden Grove, Carlisle, which was exhibited about twenty years ago at the English Agricultural Society's show, and was placed first. Before a prize is got there an examination of the beast is conducted by several veterinary surgeons. It was also shown at some other shows, and after being examined placed first. Then it was shown at the Yorkshire Society's show, and was drawn among the horses to get a prize, but when submitted to veterinary examination was condemned for having ringbone. After the horse came back Mr. Graham wrote to me to come and examine the horse. I was perfectly ignorant of what the horse had been rejected for, but I knew I would not be there unless there was a dispute, and I made my examination all the more stringent. I told Mr. Graham and his veterinary surgeon, Mr. Bell, of Carlisle, that I could not see anything wrong with the horse, and that he was very sound. He replied, "Will you be kind enough to put your hand over his hoofheads, he has been condemned for ringbone?" I went back and did so, and said "No, I cannot agree with that. There are prominent sides to the bones all round, but I do not consider he has ringbone." Unfortunately that horse died within a month or two, and a preparation was made of his bones, but not by me, neither did I see the bones, but the bones were submitted by Mr. Bell, of Carlisle, at a meeting of the North of England Veterinary Society to the members present, and there was not a vestige of ringbone, but only prominences of the bones. The formation of hoof heads and pasterns of this filly in question were just identically the same as that of that horse. They were normal, and there was not a vestige of abnormal growth. These

prominences are in some animals much more developed than in others. It is identically the same with the wrists of the human subject. I would find a considerable number of persons with much larger prominences of wrist than myself, and it might as well be said that that was ringbone. I am of opinion that the filly has very prominent processes. She is just the thing I want with good big bones, clean bones, and a big hoof head. It does not matter how good the animal may be, Clydesdale breeders won't give the price unless it has big feet, because it requires to have a big foot to carry a big body. It is also very desirable to have longish hair on the hoof head; when you have a nice quantity of hair flowing over the coronet it makes the foot look the bigger, and it is quite common to blister round the coronet to stimulate the growth of the hair.

Cross-examined: Have you come across ringbone in two-year-olds?—I have come across two-year-olds that were said to have had it, and they had not. I never examined a two-year-old or younger animal suffering from it. I have seen them said to have ringbone when it was only natural formation.

But in that case would you not have symmetry all round the bone, whereas in ringbone it might be in patches?—Yes, quite.

There is nothing impossible about finding it at two-year-olds?—No, but that would as a rule be from external injury.

Might it not be hereditary at that age?—I cannot tell, no man can tell when it is hereditary or not. It might be hereditary from predisposition.

Re-examined: Did you ever feel ringbone that yielded to pressure?—It could not; it is a bony substance.

We were told by Mr. Spruell, of Dundee, that he considered there was ringbone on this filly's fore feet, that it had been growing a year, and that it still suffered from it. Could that possibly be true?—I don't understand it. I would not like to say it was untrue, but I cannot believe it. (Laughter.)

James Lindsay, veterinary surgeon, Dumfries, said he examined the filly, Sweet Bloom, in the livery stables at Glasgow on July 24th. He made a thorough examination of the filly, lasting two hours. He moved and trotted her about. He found her absolutely sound. There was no suspicion of ringbone about her. She went sound and sweet.

Would you be surprised to hear that witnesses have said the filly has large articulation?—I would not be surprised at anything.

Mr. Hainz asked permission to put Mr. Lorimer in the witness-box to clear up the matter in regard to the application of liniment to the filly's feet.

Mr. Irving took objection to this evidence, because there was no citation, and because Mr. Lorimer was in the court while Mr. Berwick was examined the previous day, and also during part of Mr. McIntosh's evidence. He thought it was quite irregular that this witness should be called.

The Sheriff agreed to allow the evidence.

Henry Lorimer, West Linton, the present owner of the filly, said he had used the liniment on the hoof heads for the purpose of making hair grow on the filly's legs. He was advised to do this by Mr. Weir, Lanark, and he received the liniment from him.

Robert Pollock, Papermill Farm, Langside, Glasgow, son of pursuer, said that it was he who drove his father and defender from Papermill Farm to the place where the filly was grazing four miles from the farm on June 20. He was there when defender was looking at the filly. Defender examined the animal, and was clearly satisfied with it. He examined the hoofs, as any business man would do.

This concluded the evidence, and the case was adjourned for debate.

ANNUAL REPORT, ARMY VETERINARY DEPARTMENT,
INDIA, 1901-11.

The Report to hand, like his predecessors, records a long struggle against animal diseases at odds which we in Britain cannot realize—the bald figures may reach our understanding, they fail to impress our imagination. Throughout the report is the same undernote of increasing work, with little increase in men to meet it. The following extracts give an outline of the report :

OFFICERS OF THE CIVIL VETERINARY DEPARTMENT
FOR THE OFFICIAL YEAR APRIL, 1910, TO MARCH, 1911.

Inspector-General	Col. H. T. Pease, C.I.E.
	Lieut.-Col. G. H. Evans *
Imperial Bacteriologist,	Maj. F. S. H. Baldrey
	Maj. J. D. E. Holmes, M.A., D.Sc.
Assistant	H. E. Cross, Esq.
Physiological Chemist,	P. Hartley, Esq., D.Sc. (Lond.)
Supt. Government	Lieut.-Col. J. Farmer
Cattle Farm, Hissar,	E. W. Oliver, Esq.
Supt. United Provinces,	C. W. Wilson, Esq.
2nd Supt.	Maj. G. K. Walker
Chief Supt., Punjab.	V. de V. H. Woodley, Esq.
Supt. N. W. Frontier	"
Prov. and N. Punjab,	S. Carless, Esq.
Supt., South Punjab,	G. Taylor, Esq.
Supt. Sind, Baluchistan	Maj. A. S. Trydell
and Rajputana,	Maj. A. Smith
Prin. Punjab Vet. Coll.,	E. Burke, Esq.
Prof.	S. H. Gaiger, Esq.
Prof. Sanitary Science,	M. H. Sowerby, Esq.
Punjab Vet. College,	K. Hewlett, Esq.
Principal, Bombay	N. D. Dhakmarvala, Esq.
Veterinary College,	M. H. Sowerby, Esq.
Assistant Principal,	K. Hewlett, Esq.
Bombay Vet. College,	Lieut. Col. H. M. Maxwell
Supt., Bombay,	Col. F. Raymond
Prin. Bengal Vet. Coll.,	D. Quinlan, Esq.
Supt. Bengal,	W. Harris, Esq.
" E. " and Assam,	D. A. D. Aitchison, Esq.
Prin. Madras Vet. Coll.,	Capt. W. O. Dawson
Supt. Madras,	F. Ware, Esq.
" Burma,	Lieut. Col. G. H. Evans
2nd Supt. Burma,	C. J. N. Cameron, Esq.
3rd	"
Superintendent,	F. Ware, Esq.
Central Provinces,	Maj. F. H. S. Baldrey
Veterinary Officer Inves-	Col. H. T. Pease, C.I.E.
tigating camel diseases,	A. S. Leese, Esq.
Attached for training	R. Branford, Esq.
Punjab	J. G. Cattell, Esq.
	S. Carless, Esq.
Central Provinces,	Maj. W. O. Dawson *
Gov. cattlefarm, Hissar,	R. Branford, Esq. *
Bengal, Vet. Coll.,	P. J. Kerr, Esq. *

* The second name is the officer holding office, March, 1911.

VETERINARY INSTRUCTION.

Bengal. Taking the percentage of passes, the Bengal College stands first. In the first year's class, 39 students out of 50 sent up were successful; in the second, 28 out of 37; and in the final year's test 35 out of 46, giving a general average of 76.69. During the vacation, eight Army transport drivers were trained as dressers.

The number of cases in the hospital was 5869 against 5680. The fees realised for treatment, etc., amounted to Rs. 14,869-12-8. A new ambulance was urgently needed

and Babu Govindram Singhonia presented Rs. 1000 for the purchase of a conveyance.

The Principal remarks on the difficulty in obtaining funds for the further development of the College.

Punjab. In the first year's class there were 63 students of whom 48 passed; 76 in the second year, and of these 59 were successful. Out of a class of 76 in the final year 53 qualified, giving a general percentage of 74.41.

In addition to the ordinary work, a three months' course was given to 43 men from the Transport Department. A nine months' course in practical shoeing was arranged for; 22 men attended, and at the examination held on completion of the course, 16 men satisfied the examiners.

The number of cases treated during the year was 5597. The sum of Rs. 12046-11-1 was paid into the Treasury.

Madras. First year's class number presented 18, passed 13; second year 22, passed 16; and in the final year—18, of whom 10 qualified. General average 67.24 per cent.

At this College owing to the small number of pupils in each of the classes, the lecturers were able, and evidently had devoted much trouble and care to the training of the students, and the examiners were gratified to find the successful students so well up in their work.

The number of cases treated in the hospital was 2145, and the receipts from hospital charges amounted to Rs. 11,099-14-6.

The Principal has pointed out the great difficulty experienced in obtaining sufficiently educated students. During the year, after advertising the College prospectus in the Fort St. George and local gazettes, and having expended the sum of Rs. 1200 in advertising in newspapers, he succeeded in obtaining only 11 matriculates. This difficulty exists elsewhere. The task imposed on lecturers in expecting them to teach Indian students up to a certain standard, is rendered doubly difficult when in order to make up classes, they are obliged to admit students known to them to be very deficient in general education.

Bombay. 23 students presented themselves for the first professional and 15 passed; in the second year 27, of whom 21 were successful; and in the final year's class, 41 men appeared and 22 passed. General average 63.73 per cent.

During the long vacation, a class was held for the training of drivers of the Supply and Transport Corps as dressers. Thirteen drivers attended the course.

During the year, 4550 animals received treatment. Receipts amounted to Rs. 8887-10-0.

Various improvements to the College buildings have been carried out. Owing to a comprehensive scheme for the general improvement of the College premises being under consideration, the construction of certain proposed buildings has been held in abeyance.

Burma. At the beginning of the year there were 33 pupils in the School—20 in the senior and 13 in the junior class. Eighteen pupils in the senior class were examined and 14 qualified. A fresh batch of 13 pupils has been admitted.

There has been a considerable increase in the number of cases treated at Insein, 738 against 240 last year, and there seems ample reason to believe that when suitable accommodation (which at present is temporary) is provided, that a further increase may be anticipated. The work at the laboratory has also increased to a great extent owing to the large number of specimens received from all parts of the Province. The Superintendent observes that, "the efforts of the staff have been taxed to the utmost to deal with the amount of work now presented, and will be totally insufficient to cope with much further increase."

TREATMENT OF DISEASE.

The total mortality reported, as compared with the previous year, shows a decrease of 461 under "Equines," and increases of 6942 and 423 under "Bovines" and "Others," respectively.

Glanders. The number of cases of glanders reported is 229 against 236 in the previous year. Of the total number, 130 or nearly 57 per cent. were reported from Bengal. East Bengal and Assam shows an increase of 35 over last year's figures, Punjab 3, and North-West Frontier Province 2. United Provinces show a decrease of 17 and Bengal 30. Diagnosis was in all cases confirmed by the mallein test.

The policy of granting compensation to owners of animals destroyed for glanders is reported to have greatly improved the working facilities for the suppression of this disease. Measures can now be promptly taken to stamp it out.

It may not be out of place to mention here, that owing to the very serious prevalence of glanders within the municipal limits of Rangoon, especially so in the gharry stables of the town and suburbs, the services of an officer of the Civil Veterinary Department was specially asked for to assist the municipal authorities in dealing with the disease. Mr. Branford was placed on special duty on the 23rd December and remained on this work till the 15th March, when he had to leave in order to take charge of the Hissar Farm during the absence of Lieut. Colonel Farmer whose state of health necessitated his proceeding on leave.

Such work, at all times unpleasant, was rendered exceedingly so owing to the hostile attitude of native owners. I have great pleasure in reporting that Mr. Branford merits much praise for his tact and care in dealing with the people, and also for the amount of work he performed during the above-named period.

Anthrax. A decrease is reported under this heading, the number being 16,425 "Equines," "Bovines" and "Others," against 17,264 last year. Under the head "Equines" 46 deaths are reported against 51 in the preceding year. The diagnosis of cases of Anthrax reported from the United Provinces, Central Provinces, Bengal and Eastern Bengal and Assam, was confirmed by bacteriological examination.

Surra.—The total mortality recorded is 767 against 1,126 last year. After the annual report had been sent to the Press, 417 cases were reported amongst mules and ponies in Burma, of which 312 cases were recorded in North Shan States, 78 in South Shan States, and 27 in Burma. Surra is believed to have been rife amongst caravan animals returning from Chiengmai (in Siam) and to have been generally prevalent along the Burma-Siam frontier.

There is no question that many more cases occurred than those recorded.

Other contagious diseases.—The number of cases reported under this head amounts to 46,542 against 47,143 last year. No details, however, as to the nature of these ailments have been furnished.

Rinderpest.—The number of deaths reported this year is 156,978 against 158,425 shown in last year's returns.

Foot-and-mouth disease.—A decrease is shown under this head, the figures being 25,548 against 27,041 last year.

Hæmorrhagic Septicæmia and Black-quarter.—The total number of deaths recorded under these two headings is 63,413 against 52,370 last year. Preventive inoculation against these diseases was adopted with encouraging results.

Other contagious diseases met with among animals in addition to those already specified, were distemper, rabies, and contagious pleuro-pneumonia. Increases are recorded under rabies and pleuro-pneumonia.

Camels.—Some items of interest from a detailed report which has been submitted, are as follows: Mortality in 8 Silladar Camel Corps now down to 13·3% on an average strength of 8,230 camels, which is satisfactory. A very interesting note on surra spreading in the sandy desert of the Bikanir State. That camel surra may spread in years of unusual rainfall in this desert is rather a startling fact. No such outbreaks have been observed in the deserts of the Punjab. The only species of biting fly present was a *Lyperosia* (*Lyperosia minuta*, Bezzi). These flies occurred in swarms on every camel, particularly favouring the lower portion of the neck, region of the hump and knees. They are a source of great annoyance and cause intense irritation. *Lyperosia* appear to have only once before on good grounds been suspected as a transmitter of surra, i.e. amongst cattle in Rhodesia (Kinghorn and Montgomery). It is clear that this outbreak occurred in the absence of *Tabanus*, *Stomoxys*, or other biting flies.

Mr. Leese has continued to devote himself wholeheartedly to the study of surra and its treatment. Every endeavour is being made to supply him with affected camels in a condition fit to undergo treatment, in order that he may have ample material to uninterruptedly pursue his investigations. Some cases have apparently been cured, but in regard to statements of cures in camels much caution is desirable owing to the peculiar characters of the disease in these animals. The treatment considered most promising is by the use of Atoxyl and Tartar emetic (intravenously), and Sodium Arsenate solution (per os).

Bilharziosis.—During a search for adult filariæ a parasite was found in the mesenteric veins of the large intestines which proved to be *Schistosomum indicum*. (Identification confirmed by Dr. Leiper, of London School of Tropical Medicine). Subsequently it was found in five out of eighteen camels examined. It would seem the parasite is only of practical importance when the infestation is severe.

Peritonitis.—Last year a specific peritonitis was met with in Montgomery district. The larvæ of the *Linguatula tenuoides* are extremely common in camels and show a predilection for the group of glands draining the cæcum and colon. This year a case was again met with and there seems little doubt of their association with peritonitis in the camel. A post-mortem examination revealed the glands of the cæcum and colon intensely inflamed. They contained large numbers of larvæ and were full of cavities which had been occupied by parasites; many of these cavities opened on the outer surface of the glands. No free larvæ were found in the peritoneal cavity nor was there any enteritis nor any other channel of infection found. The functional destruction of the glands would appear to have allowed access of bacteria from the intestine to the peritoneum. Last year, hæmorrhage from the nose was observed as an occasional symptom.

Mr. Leese has been most energetic and unremitting in his labours to advance our knowledge of the diseases of the camel. Considering that his work has been carried out often in trying circumstances, the success achieved is highly commendable. I consider we are greatly indebted to him not only for the zealous manner in which he has carried on his work, but also for the progress made.

The number of veterinary assistants employed has increased by nearly a hundred, viz., from 517 to 614. With the exception of Rajputana, additions have been made in every Province. Madras shows 38 veterinary assistants now employed. In last year's report none were recorded. Over 11,000 more villages were visited, and the number of cases treated (excluding castrations) exceeded those of last year by 63,741. There were 327 veterinary dispensaries in working order during the

year under report. In Rajputana and Bengal the numbers remain the same as last year; in all other Provinces there is an increase shown.

BACTERIOLOGICAL LABORATORY.

Major F. S. H. Baldrey officiated as Imperial Bacteriologist until the 4th November, 1910, on which date Major J. D. E. Holmes assumed charge. Mr. H. E. Cross and Dr. P. Hartley held their respective charges of Assistant Bacteriologist and Physiological Chemist. The three European Laboratory Assistants held their respective appointments during the year.

Preparation of Sera.

Rinderpest anti-serum.—The number of doses of anti-rinderpest serum prepared during the year amounted to 577,969 as against 409,078 manufactured last year, roughly an increase of 169,000 doses. The issue of serum amounted to 533,799 as compared with 446,981 during the year 1909-1910.

The demand for serum increases each year and is far greater than the output. Many indents could not be complied with at all, or only in part. It is interesting to find that the use of serum is being so much appreciated in Native States. In Mysore some 27,000 animals have been injected during the past three years, and so great is the popularity of the method that at times it has been impossible to meet the demands, and this has raised the question of providing another laboratory for serum preparation.

Anthrax anti-serum.—During the past year 5,415 doses were prepared against 12,168 during the previous year. The issue amounted to 9,715 doses against 12,404 of the previous year. Its preparation was regulated according to the demand in the field. Investigations regarding the practical value of anti-anthrax serum and vaccines have been conducted during the past two years and a preliminary report will be published shortly.

Hæmorrhagic Septicæmia.—50,350 doses of Hæmorrhagic septicæmia vaccine were prepared and all issued, as against 8,320, or 42,030 doses more than in the previous year. No unfavourable reports were received with regard to the efficacy of the vaccine, and the figures show satisfactory results.

Charbon Symptomatique.—33,400 doses of single vaccine in pillule form were prepared; 19,900 doses of vaccine and 536 of serum were issued to the various Superintendents. The vaccine prepared at the laboratory appears to be very efficacious. The mortality in animals vaccinated in the Punjab amounted to '07, whereas in untreated animals, the usual death-rate is something like 88%.

Strangles.—During the past year 1,829 doses of anti-streptococcus serum and 500 doses of vaccine were prepared. The total issue of these products amounted to 1,617 doses. This serum was prepared to meet the demand from the Army Remount Department, but no definite results have been reported to this Department.

Mallein.—Twelve thousand nine hundred and forty-one (12,941) doses of mallein were prepared, against 9,515 doses during the previous year. With a balance of 2,730 doses from the previous year and 598 returned from the field as unused balance, the total issue amounted to 16,229 doses.

Tuberculin.—During the year under report 209 doses of tuberculin were prepared and 188 issued.

Specimens examined.—Two hundred and ten (210) specimens were received for examination and report during the past official year, against 84 during the previous year.

Training of Veterinary Assistants.—Seventeen Veterinary Assistants attended the course of training, eight at Muktesar and nine at Bareilly, against 36 during the past year. The decrease is due to the facilities now

afforded in the Veterinary Colleges for training students in inoculation work.

As already noted, the whole staff—superior and subordinate—have had very hard work throughout the year, indeed the pressure at times has been so great that a number of members of the staff have had to be employed from daylight to dark daily, including Sundays and Gazetted holidays. The Imperial Bacteriologist records his appreciation of the excellent work and co-operation of the whole staff, and I have much pleasure in endorsing his remarks.

Much credit is due to Majors Holmes and Baldrey, Mr. Cross and Dr. Hartley for having, under trying circumstances, accomplished so much during the year.

GOVERNMENT CATTLE FARM, HISSAR.

Lieut.-Col. J. Farmer held charge throughout the year under report. The operations at the farm have on the whole been successful.

It was handed over temporarily to the Civil Veterinary Department on the 1st April, 1899, and was transferred permanently to the Department on the 1st April, 1910. There is no denying that during the above-named period the farm in its various branches has been vastly improved, and financially it is perhaps now in a more satisfactory state than at any time during its history.

Conditions, however, exist which render it almost impossible to make the farm all that could be desired. It is most unfortunate that at the time the farm was started, those responsible failed to close all public highways passing through the acquired tract of country. The result of such an omission has made the charge of the Hissar Farm both an anxious and highly responsible one. In spite of all possible precautions, with disease at times prevailing all around, infection through the agency of diseased animals from without occurs from time to time. Owing to unremitting attention the outbreaks are few, and in recent years the farm has escaped the severe ravages committed by contagious maladies in days gone by. During the year cases of the following diseases were reported, viz., Rinderpest, Foot and mouth disease, Black quarter, Strangles, and Sheep-pox. As a result of the prompt action taken by the Superintendent, the outbreak of rinderpest was rapidly checked and only one death was reported.

If the fact that a large amount of the stock bred at Hissar is issued to Government Departments at prices very far below that obtainable from private purchasers or in the open market is taken into consideration, the farm may be said to be practically self-supporting.

Lieut.-Col. Farmer has as usual worked hard and afforded ample proof of his being particularly well suited to fill the appointment of Superintendent. Any success attained is mainly due to his zeal and untiring supervision. He records his appreciation of the good work performed by his staff, more particularly Lieut. R. Morris, farm overseer, and Mr. E. MacCutchan, the farm bailiff.

There is little doubt that the work has increased to an extent that the Superintendent is much overworked. If in the interests of the farm alone, it would seem expedient that a second officer be appointed permanently to be trained under Lieut.-Colonel Farmer, who stands alone in his knowledge and experience of the Hissar Farm. Should any circumstance arise necessitating Colonel Farmer relinquishing charge of the farm, unless there is an officer thoroughly conversant with the various duties connected with this special charge ready to immediately take up the work, I fear it would not be long before neglect of this precaution was very forcibly impressed upon us.

GENERAL.

Work continues to increase and it is questionable if the Imperial staff can accomplish any more than is now

being done. It would, however, appear in several Provinces that Superintendents have a large amount of office work to get through. It is to be feared the tendency is, to look upon such and administrative duties as matters of the first importance. Experience teaches that the amount of office work instead of diminishing year by year increases enormously, and Superintendents are being prevented (or can at least make it an excuse) from devoting themselves to the essential part of their duties, viz., field work. Unless measures be taken to curtail the office work there is every prospect, and that in the near future, of Superintendents blossoming into Deputy Directors for veterinary work. The aim and object of their appointments thereby being to a great extent frustrated. Superintendents are experts and are very few in number; their energies should be concentrated on veterinary, and not be dissipated in clerical work, to do which, many other cheaper and perhaps more efficient agencies are available. In order to perform veterinary work proper in an efficient manner, it is imperative that they be free as possible to employ their time in special work and pursue it among the agricultural classes. Superintendents who do not spend the greater portion of the year going about their respective charges, helping the people during outbreaks of cattle disease, and enquiring into all matters affecting agriculture from a veterinary standpoint, but who entrust such important duties to subordinates without thorough supervision, will not, in my opinion, be in full sympathy with the welfare of cattle owners, and must fail in the special purpose for which they are appointed. Most of the routine office work can be well done by others not possessed of their special knowledge.

Fully qualified Veterinary Surgeons for district work in India, Assam and Burma number 17.

Veterinary Assistants trained in Indian Schools and Colleges, when first put to district work, naturally are far from being qualified to perform the real work required from them. Central Colleges situated as they are in large towns cannot provide the experience necessary. The most important part of their training must come after they have left the Colleges, and it is the District Superintendents alone who can afford them this special training. It certainly cannot be done by writing from headquarters. It is rarely in Colleges that opportunity occurs of affording pupils practical instruction in that all-important work dealing with epidemics, and the same remark applies equally to the local hospitals. It can only be imparted in the villages, grazing grounds, etc., while epidemics are prevailing and as soon as possible after the outbreak has occurred. To carry out such work a Superintendent must be willing and free to leave his head-quarters at any time, and himself supervise and help in as many outbreaks as possible. When there are no epidemics Superintendents can find plenty to do in looking after the work of Assistants and instructing them how to deal with outbreaks at the onset, before their superiors can arrive, and when they must necessarily act on their own initiative."

The report is signed by G. H. Evans, Lt.-Col., Offg. Insp. Genl. C.V.D., Simla, Sept. 30, 1911.

OBITUARY.

GEORGE BARRAS, M.R.C.V.S., Aiskew, Bedale (late of Princes Risborough) Graduated, Edin: May, 1899.

Mr. Barras died on Nov. 12th, from phthisis pneumoniae. Aged 35 years.

CHARLES COLEBROOK, M.R.C.V.S., Basingstoke, Hants. Lond: May, 1861.

Death occurred on Nov. 13th, from carcinoma of stomach, at the age of 77 years.

PARLIAMENTARY.

FOOT-AND-MOUTH DISEASE. APPOINTMENT OF COMMITTEE.

In the House of Commons, on Wednesday, Nov. 15.

In answer to questions by Mr. C. BATHURST.

Mr. RUNCIMAN (Dewsbury): The Committee will consist of 12 members, who have been requested to inquire into the circumstances of the recent outbreaks of foot-and-mouth disease, and to consider whether any further measures can be adopted to prevent their recurrence. The Right Hon. Sir Ailwyn Fellowes has consented to act as Chairman of the Committee. The following are the other members who have consented to serve:—The hon. member for South Wilts, Mr. Richardson Carr, of Tring, Hertfordshire, Major E. Marten Dunne, of Gatley Park, Kingsland, Herefordshire, the hon. member for the St. Patrick's Division of Dublin, the hon. member for Barkston Ash, the hon. member for Carmarthenshire West, Mr. E. E. Morrison, of Bonnytown, Stravithie, Fifeshire, Mr. E. P. Nunneley, of Wellingborough, the hon. member of the Newmarket Division of Cambridgeshire, and the hon. member for North Bucks. I am endeavouring also to secure the assistance of a member of the Central Chamber of Agriculture. The Veterinary and Administrative officers of the Board will give the Committee every assistance. I desire, however, to arrange for the prosecution at the same time of an expert scientific inquiry into the more obscure characteristics of the disease, an inquiry which this Committee cannot be expected themselves to undertake. I am informed that the Indian Empire, where the disease is more prevalent than is, happily, the case in this country, affords a wide field for an investigation of this specialised character. I am in communication with the India Office on the subject, and I hope that it may be found possible to arrange with the Indian Government for the constitution of a small Scientific Commission consisting of two experts from this country, with whom may be associated, if the Indian Government approve, an equal number of experts appointed by them, to visit India and to study in that country the characteristics of the disease, its etiology, the means by which it is contracted and spread, and practicable means of prevention. I am aware of the difficulties which may beset the further inquiry which I propose to set on foot; but I believe that the great interests of this country in valuable live stock, and of India also, justify a more thorough scientific investigation than has been made up to the present. I am convinced that by these means we shall most effectively mitigate the loss and inconvenience suffered not only by agriculturists, but also by those whose business transactions are hampered by the restrictions which these outbreaks make it necessary to impose upon the free movement of agricultural produce.

Personal.

Mr. J. H. CARTER, F.R.C.V.S., was unanimously appointed Chairman of the Highways and Sewage Committee, at the meeting of Corporation Committees, Town Hall, Burnley, on Monday last.

The naval medical service of France still uses leeches, and in connection with this fact M. Boyer tells an amusing story. A jar of leeches was bought in 1907. Each leech when taken out has, it appears, to be signed for by the doctor. It came to pass that five leeches died a natural death without the medical certificate. It took two years of enquiry, a vast amount of correspondence, references to commissions, and reports to Ministers, to get the matter finally settled, and the death of the five leeches officially authenticated.

"Marvellous Results in Pneumonia."

NUCLEIN (P., D. & Co.), when administered to animals, produces an enormous increase of leucocytes in the blood, and thereby greatly enhances disease-resistance. Hahn states (*Berlin. klin. Wochenschr.*, Nov. 28, 1896) that with Nuclein (P., D. & Co.) "it is easy to double the original number of leucocytes in a short time. This remarkable property renders the drug of great value in the treatment of

Pneumonia Pleurisy Strangles Purpura Hæmorrhagica Umbilical Infection
Influenza Lymphangitis Laryngitis Wound Infections Epizootic Cellulitis
 and other Pathological Changes due to Bacteria.

VETERINARIANS' REPORTS.

Pneumonia.

E. R. VOORHEES states in the *American Veterinary Review* that Nuclein has produced results which at times "seemed marvellous," and instances an apparently hopeless case of double pneumonia which recovered rapidly after the injection of Nuclein. Also see article by E. M. PERRY in *The Veterinary News* of Nov. 19, 1910, and by D. HANNAY in *The Veterinary Record*, Mar. 11, p. 589.

Fistula, Poll Evil, Septicæmia.

A report appears in *The Veterinary News* of Feb. 4, 1911 (p. 67), of the prompt improvement brought about by Nuclein in cases of fistula and poll evil which had failed to respond to other methods of treatment. A case of profound toxæmia in a dog which was greatly benefited by Nuclein is reported in *The Veterinary News* of Feb. 16, 1907 (p. 109).

NUCLEIN SOLUTION (P., D. & Co.) is supplied in bottles of 1 and 4 fluid ounces, also in hermetically-sealed glass bulbs containing one dose diluted with physiological sodium chloride solution suitable for intramuscular injection.

NUCLEIN SOLUTION No. 2 (P., D. & Co.), for oral use, is supplied in bottles of 4, 8 and 16 fluid ounces.

**The FINALITY of
Hypodermic and Serum Syringes.**

"The **"Record"** Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

PRACTICES FOR DISPOSAL

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

HOME COUNTY. Receipts £350 to £400 per ann. Rent £35. Premium required £200.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SCOTLAND. Returning over £300 per annum. Expenses very low. Premium £120, or nearest offer.

YORKSHIRE. Receipts 1910 £332. Rent £19. Premium £300.

ROYAL (DICK) VETERINARY COLLEGE, Edinburgh,

Appeal for Funds towards New College Buildings and Equipment.

THE BOARD OF MANAGEMENT beg to draw the attention of the Public to this important National Scheme, involving an expenditure of about £50,000, and to solicit contributions to enable them to complete arrangements for the commencement of Building Operations at an early date—a Site at Summerhall, situated at the east end of the Meadows having been acquired for this purpose.

Subscriptions to the amount of £20,006 10s. have already been intimated. The Scotch Education Department has promised to contribute (up to the sum of nearly £25,000), an equivalent to the amount raised by subscriptions. The sum, therefore, now required to complete the Scheme is £5000.

LIST OF SUBSCRIPTIONS INTIMATED.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1220.

NOVEMBER 25, 1911.

VOL. XXIV.

THE COLLEGE CREST APPEAL FUND.

We understand that the appeal case regarding the use of the College crest by members, L.C.C. v. Kirk, will come on for hearing within a few days' time. All members who intend subscribing to the defence fund which is being raised, and have not yet done so, should therefore at once forward their subscriptions to Prof. Woodruff at the R.V.C., Camden Town. Considering how large a number of our members habitually use the College crest, the amount already subscribed towards the effort to retain it is certainly very meagre indeed.

THE C.V.D. ANNUAL REPORT—A CORRECTION.

By an unfortunate printer's error, the abstract which commenced on page 317 of last week's issue was headed "Annual Report, Army Veterinary Department, India, 1901-11." It should of course have read "Annual Report, Civil Veterinary Department, 1910-11." We regret the mistake.

THE C.V.D. CENTRAL PROVINCES, INDIA.

The Annual Report, 1910-11, illustrates, even more forcibly than such documents usually do, the overworked and undermanned condition of this Department, which is nevertheless rendering such invaluable service to India.

During the year the work has extended very rapidly—the number of cases treated at dispensaries increased by 24%, and the number treated on tour by fully 50%. But during the same period the staff of veterinary assistants has only risen from 82 to 86; while the Chief Superintendent, Major Baldrey, was absent for seven months on deputation duty at Muktesar. During his absence the Assistant Superintendent, Mr. Ware, took entire charge, this practically meaning that for more than half the year the two offices of Chief and Assistant Superintendent had to be discharged by one man. Major Baldrey himself in his report, the Director of Agriculture in a covering letter, and a Governmental resolution upon the report, alike concur in emphasising the disadvantages arising from this, and it seems probable that a repetition of it may be avoided.

The incidence of animal disease in the Central Provinces varies a little from that in other parts of India. Only four outbreaks of surra were reported in the year, and none at all of glanders, epizootic lymphangitis, and epizootic abortion. By far the most fatal diseases are rinderpest and hæmorrhagic septicæmia. The former is now abating; but the latter has appeared in every district, and there is no doubt that in former years it was often mistaken for anthrax or black-leg. Anthrax and black-leg are not now so common as they once were, or were thought to be, but foot-and-mouth disease is still very prevalent. Major Baldrey strongly believes hæmorrhagic septicæmia to be insect-borne; but so far he is unable to directly prove this, and remarks that the pressure of routine and diagnostic work renders research almost impossible to him. Considering this officer's

exceptional record of research work at Muktesar and elsewhere, it is a thousand pities that he should be practically debarred from it in the Central Provinces.

Throughout India, the need of the C.V.D. is the same. More and better trained assistants are wanted for the field, more superintendents are wanted to cope with the ever-expanding preventive work, and a few selected men of the latter grade should be left free to devote themselves to research. Happily we have now abundant evidence of an increasing Governmental recognition of these needs, which the covering letter and resolution we have mentioned agree in admitting; and we are glad to see that both these official documents make very special commendatory mention of the good work which is being done by Major Baldrey.

DONATIONS TO R.C.V.S.

"The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following second year's donation to the College funds from

Mr. G. Garnett, Hove, Sussex, £1 1 0

Twelve months ago Mr. G. Garnett anticipated the action of the V.S. Act Amendment Bill—still, unhappily, on the knees of the gods—by initiating an annual donation of the amount of the proposed Annual Fee. His example was followed by other members, their action was acknowledged by the Council R.C.V.S., and the result was a net gain of £90 to the College funds. Since then the steady depletion of the College funds has continued, and there is no prospect of more than a slight recovery in the value of Government securities in which the College funds are invested. Well-wishers of the R.C.V.S. may therefore look to a continuance and an increase of the assistance voluntarily rendered last year.

The outlook for the general body of the profession, in event of the V.S. Amendment Act failing to become law before the limit of our reserves is reached—which may well arrive from several causes outside the opposition offered by a few members of the "anti" persuasion—is not a cheerful one. The power of granting Diplomas might be absorbed by several wealthy Universities who are always ready to add to their powers—instead of being in the hands of members elected by members, as at present. It were well that more of our men should examine and recognise the reasons in favour of upholding their College. Never was the old motto of the sword hilt more appropriate—"Who gives quickly gives twice"—and in this case the sword blade is money.

NECROBACILLOSIS IN THE DOG.

By HENRY GRAY, M.R.C.V.S.

Synonyms.—Fistulous dermatitis. French: *Dermatite phlegmoneuse et fistuleuse*.

History.—This disease has frequently been observed, but rarely described. Attention has been called to it by Cadiot and Almy, Cadiot and Breton, and the writer. But the credit of pointing out its true cause and nature is due to Cuillé, who has given a very good description of it. Livesey has also recently referred to it, or, at least, to one form of it.

Animals affected.—It is mostly seen in the larger lymphatic breeds, and in sporting dogs, and occasionally in other breeds and in the cat. It is well-known in the other domestic animals and in the rabbit and hare, in which latter animals it often occurs as an enzoötic or as an epizootic.

Seats of election.—It seizes by preference the tail, the circum-anal skin and tissues, the feet, hock, the outer surface of the regions of the stifle, elbow, and fore-arm, the sheath, nose, and lips. In the cat, the feet and tail. In the monkey, it generally affects the tail.

Etiology.—The infection gains entrance to the tissues by inoculation, wounds or abrasions, which are frequently caused by sharp-pointed or cutting bodies and occasionally by the *demodex folliculorum*. In the region of the feet it gains an entrance through the wounds set up by thorns, barley grass, other plants, and injuries. In the hare and rabbit it may arise from ingestion of the bacillus.

The bacillus *necrophora vel necroseos* or, bacillus of Bang, or of Löffler, is generally accompanied by other microbic infections, such as the streptococcus and staphylococcus. It may complicate distemper and lesions in the mouth and cheeks.

Symptoms.—It usually commences by swelling of the skin which becomes purplish and hairless. After a short period abscesses varying in size from a small pea to a walnut, or even to that of a fowl's egg, form in the subcutaneous connective tissue, burst, and discharge a dirty, bloody purulent fluid. The resulting wounds have no tendency to heal, but leave deep fistulous channels which continually discharge a thick bloody purulent material mixed with shreds of necrotic tissue. The skin remains thick and hairless. The fistulous openings often seem as if punched out, and give the skin the appearance of a strainer or collander. The disease rarely extends, but usually remains stationary without showing any inclination to heal. However, the writer* has seen many cases that have become generalised; and Cadiot and Almy observed a case commencing at the sheath, extending to the groin and the whole of the right thigh, and leading to a fatal peritonitis. In generalised cases, the skin has generally a lacerated appearance after the abscesses have burst and discharged their contents.

*The Treatment of Canine Distemper. *Hoare's Veterinary Therapeutics*, pp. 675 and 697, 1906.

When the disease commences between the digits lameness is at first observed and often the affected limb is carried. The space between the toes becomes swollen, red and then purplish. Pain is caused by manipulation and the skin shows some oozing. The swelling is produced by several abscesses which burst and discharge a bloody purulent fluid. The resulting wounds do not heal up, but take on a fistulous character and discharge a bloody serous material. Often when one thinks the wound is almost healed up the region above the digits extending to that of the hock or carpus, or even above these regions commence to swell, become hot and painful and eventually several abscesses form and burst and the resulting cavities communicate with one another. Often one is able to pass a fine probe several inches up the limb from the inferior or digital wound. Occasionally the chain of abscesses extends up the limb to the groin or axilla, burst and give rise to several wounds discharging bloody pus. The fistulae are kept up by the necrotic lesions of the aponeuroses, tendons or bones.

Two or more or all the limbs, to which the disease in this form is usually confined, may be affected at the same time. Generally only one limb is attacked.

The disease when confined to certain parts does not as a rule interfere much with the general condition of the animal. In generalised cases, however, it may produce emaciation and even death from exhaustion. When it affects two or more limbs at the same time, the animal usually persists in assuming the recumbent position.

The disease is generally very slow in disappearing. In the case of the limbs, beyond opening the fistulous openings and applying iodine dressings, Bier's treatment has given the writer good results. Where this latter method cannot be adopted, nitrate of silver, sulphate of copper, biniodide of mercury, peroxide of hydrogen, or even creolin in a pure state has been followed by successful results. Arsenic should be given internally.

The tail is the most troublesome organ to treat, as nearly every practitioner too well knows. The same may be said of tissues round the anus.

The generalised cases are not always the most troublesome ones to treat. The majority of cases affecting the limb in the cat succumb.

The writer trusts that those practitioners interested in this subject will record their experiences. It is with this object in view that this article is published.

TETANUS IN A PONY—RECOVERY.

About the end of last August a friend of mine who is a member of the College but not in practice, called on me asking if I had any of Hewlett's Tetanin, as his pony was showing signs of tetanus; it had fallen and cut its knees three weeks before. Not having any serum by me that I could guarantee fresh, I wired to London for some; this was on a Saturday about noon, so of course I did not get it until Monday night. In the meantime (next day) at my friend's request I drove over, and found the

symptoms very pronounced, but the patient could just manage to eat a very sloppy mash. I advised Acid hydrocyanic oil in drinking water, also 5i. of same in a quart of water as enema three or four times daily. I sent the Tetanin over on the following Tuesday, and heard no more until October 15th when to my surprise I received a letter saying "the old pony is quite well, and at work pumping water—I did not use the serum after all, but kept on with original treatment."

Now for the most interesting feature of this case, if the pony should be alive next spring, he will be 31 years old.

J. E. PORRETT.

Loddon, Norfolk.

ACORN POISONING.

By HENRY TAYLOR, F.R.C.V.S., Haywards Heath.

In the County of Sussex the oak tree has been described as the "Sussex weed," because, I presume, it grows in such profusion. This year there has been an extraordinary crop of acorns, and in consequence a high percentage of cases known as acorn poisoning. There are one or two features in connection with the condition which offer some difficulty in the matter of explanation.

At the outset the symptoms resemble indigestion and constipation, then ensues a diarrhoea with very fetid watery motions, coupled with polyuria, the urine being almost as clear as water. This leads to a gradual wasting away, the animal develops sores round the nostrils and sometimes round the mouth, becomes weaker and weaker, and finally succumbs.

What is the nature of the toxin or deleterious substances present in the acorn?

During some seasons the acorns are almost as plentiful, yet the cases of acorn poisoning are uncommon. Perhaps we may explain this by the assumption that the toxic material has, owing to meteorological conditions of the particular season, not been formed in as great an amount. Sometimes clots of blood are passed, which are such a size that there must in all probability be an actual erosion of the mucous membrane, and yet a gallon of acorns may be fed daily to a two-year-old bullock, if ground and mixed with other food, not only with no harm but with benefit. Perhaps the toxic substances may so lower the vitality of certain portions of the mucous membrane that the bacterial flora naturally present in the bowel attack it and make a breach in it.

Frequently the diarrhoea of this acorn poisoning does not come on for five or six days after the animal has been eating acorns, during which interval it may have been kept in, and consequently not have eaten any more. Their rate of digestion is apparently slow therefore. The colour of the faeces is at first black, almost as black as ink. I have heard it described as "black scour," but later on, when the animal is getting weaker and weaker, the diarrhoea is of the ordinary brown colour; yet, as the animal has been kept from eating any more

acorns one would think the cause had been removed.

Why does the diarrhoea persist? I think the partial explanation lies in the fact that the mucous membrane of the small intestines has become affected with a chronic catarrhal inflammation.

The fourth stomach, on two occasions, has appeared almost normal, and in one instance I examined the contents under the microscope for strongyles, in case the diarrhoea might be caused by parasitic gastritis, but the result was negative. Even when the post-mortem examination is made at once, one finds that portions of the mucous membrane of the first three stomachs are easily detached, but that the underlying subcutaneous tissue is not much reddened, as is seen in some conditions due to other causes. The abomasum may or may not be full of dry food. Frequently all traces of acorns have disappeared.

With regard to treatment, in the later stages, most medicines seem to be ineffectual. Iron in the form of Liq. ferri perchlor. has been recommended, but it does not appear to surpass any ordinary astringent. I have also tried many intestinal disinfectants, e.g. chinisol (five grain doses), sodii hypsulph., tannoform, creosote, ol. menth. piperitæ, and I am not sure that creosote and chinisol have not had some beneficial effect.

As soon as the farmers find that an animal has partaken of acorns, in addition to giving them a purgative, they allow the animal large quantities of hay, in the belief that hay induces rumination, and rumination assists in the digestion and elimination of the acorns.

This season I have had thirteen cases which either proved fatal or which would apparently end fatally. This is in addition to numbers which were running along with the cases which made up the above mentioned thirteen, and which were simply pointed out to me as being slightly affected, and which the owners themselves had treated.

ABSTRACTS FROM FOREIGN JOURNALS

INVAGINATION OF THE DUODENUM INTO THE STOMACH IN THE HORSE.

Grebe, of Bonn, records the following peculiar case to which he was called. The history was that the horse, on the previous evening, had shown a slight attack of colic, which had quickly passed off; and the animal had been apparently normal when left for the night. Early the next morning, however, he was found to be suffering from violent colic.

When examined by Grebe, the horse was very restless, and the whole body was covered with cold sweat. The animal pawed the ground violently and walked about continuously, but avoided lying down. Sometimes he would commence to lie down and almost do so, and then hastily rise again.

The conjunctivæ were brick red. The pulse was small, thread-like, faintly perceptible, and counted 93 per minute. The rectal temperature was 103.4°F.

The flanks were drawn up, and there was no accumulation of gas in the divisions of the intestine. Peristalsis was distinctly audible at both sides of the body, and was only a little suppressed. Rectal exploration gave completely negative results.

The horse died five hours later. The owner informed Grebe that tympany set in an hour before death. The post-mortem examination, made six hours after death, resulted as follows:—

The carcase was slightly tympanitic. The abdominal cavity held no abnormal contents, the intestinal divisions being moderately filled with alimentary material of normal colour and consistence. The vessels of the peritoneum were injected. The peritoneum itself was smooth, glistening, and transparent everywhere except in the neighbourhood of the pylorus, where it was dull, opaque, and covered with a fine and easily detachable exudate. The stomach was exceedingly tympanitic; and, when it was opened, it was found to contain a sausage-shaped invagination of the duodenum about 18 inches long.

Evidently this invagination had arisen as a result of reversed peristaltic action. Grebe, however, could not find any pathological lesion in the intestine to which the reversal of peristalsis could be attributed.—(*Berl. Tier. Woch.*)

W. R. C.

[I am not aware that this lesion has ever before been recorded in the horse. The author does not claim it as unique, but it must at least be extremely rare.—TRANSL.]

CENTRAL VETERINARY SOCIETY.

An ordinary general meeting was held at the Holborn Restaurant, on Thursday, Nov. 2nd, Mr. R. J. Foreman, President, in the chair.

The minutes of the previous meeting were taken as read and confirmed.

ELECTIONS AND NOMINATIONS.

Messrs. GEO. GORDON, J. FRANK MACDONALD, and J. D. WOOD were unanimously elected Fellows of the Society.

Messrs. J. W. SUGDEN, Southminster; A. G. GOSLING, and C. A. M. CUNNINGHAM, 128 Goswell Road, E.C.; T. A. B. COCKSEGE, Emsworth, Hants., were nominated Fellows of the Society, and will come up for election at the next meeting. The proceedings then closed.

THE ANNUAL DINNER.

Immediately following upon the meeting of the Society the annual dinner was held, to which 83 sat down, Mr. R. J. Foreman presiding. For the first time in the history of the Society ladies were present at the dinner, and the company was therefore a larger one than usual.

Following an excellent dinner, the President proposed the usual loyal toasts, which were accorded musical honours.

Mr. W. PACKMAN, in proposing the toast of "Success and prosperity to the Central Veterinary Society," said he was told the Society had about 150 members. Personally he thought the number ought to be nearer 350, as he could not understand any members of the profession keeping entirely outside veterinary politics. He

could only wonder why those gentlemen did not come in and mix with the other members of the Society as they ought to do. (Hear, hear). There was consolation, however, in the fact that the same state of affairs existed in the medical profession until Mr. Lloyd George brought in his Insurance Bill, and that closed their ranks at once. (Laughter). He wished an Insurance Bill or some other bill would close the ranks of veterinary surgeons a little bit more. (Laughter). The Society had been blessed in the past with very excellent Presidents, and the newly-elected President was a very excellent choice. (Hear, hear). He was a very great friend of his own, who once resided in the North of England, and he assured the Fellows that the President there made friends with everyone with whom he came in contact. It was evident that the same friendship had been shown to him in the South, by the Fellows of the Society electing him to the Presidential chair. (Cheers). He wished the President every prosperity and a happy year of office. The Society was also blessed with a very energetic Secretary. (Cheers). Without a good Secretary things always fell very flat, and he therefore hoped the Society would long be able to retain Mr. MacCormack's services. (Cheers). He also desired to be allowed sincerely to congratulate the Society upon the innovation of inviting ladies to be present at the annual gathering. (Cheers). He hoped other Societies would follow such an excellent example. The ladies in the past had only been allowed to see the menu when it was shown them the same night or the following morning; but they now graced the table, and were allowed to see the card in its proper place. (Cheers).

The toast was drunk with enthusiasm, "For he's a jolly good fellow" being heartily sung.

The PRESIDENT, who was very cordially received on rising to respond, thanked Mr. Packman and the ladies and gentlemen for the hearty way in which the toast had been given. He was so embarrassed that if he had not been representing the Society he would have felt inclined to make a bolt for it. (Laughter). He was always under the impression that Mr. Packman had kissed the Blarney Stone in his youth, but he knew now that that gentlemen carried a piece on his watch chain and saluted it occasionally. (Laughter). Perhaps the Society, as a body, was deserving of all the praise that Mr. Packman had accorded to it, but he was sure the honorary officials, particularly the Secretary and the Treasurer, did. They were like fathers in looking after its interests, and the Fellows were like good children in their hands until they tried to get papers and money from them; and then the Fellows were like children at medicine time. (Laughter). Why, he really could not say, because the Society was, he believed, the largest and richest Society in the veterinary profession, and contained within its ranks many of the leading lights of the profession. He really thought the reports of the meetings out to be printed, published and distributed at a fee to non-members of the Society as a kind of supplementary post-graduate course. (Laughter). The Society was in a very flourishing condition, and its popularity was undoubted, judging from the constant influx of new members. A previous Past-president had stated that the Society had existed since 5 B.C. (Laughter), and as that statement had not been contradicted he accepted it as a fact, because people were only too ready to contradict untrue statements. (Laughter). Again, 10 Red Lion Square, where the meetings were held, had been improved by the installation of a telephone, electric light, and a musical fan. (Laughter). Then the Holborn Restaurant was still in the same old spot for the annual dinner. (Laughter). Most people would be quite satisfied with the little list of attractions he had given, but the Fellows of the Society were not; they wanted the presence of the ladies at their annual social gathering

(Cheers), and he thought they were quite justified by the result. It only remained for the ladies to convert the woman-haters in the ranks of the Society, of whom there were a number. (Cries of "Shame.") He thought if they had been present that evening they would have been converted. He had always been under the impression that Presidents were elected from married men, as being very experienced individuals, or from gentlemen of imposing presence. (Laughter). After he was elected President it struck him that neither of those qualifications applied to him; that he must have been elected on account of his age, and that therefore he must be very much older than he thought he looked. (Laughter). Anyhow, he had been selected for the honour, and but for the little sad home truth about the age he was happy indeed in occupying the chair. He thanked all present for the very kind thoughts they had for the Society, and hoped they would be spurred to greater efforts in the future for it and the profession at large. (Cheers).

Mr. J. OLLIS, Chief Officer, Public Control Department, L.C.C., in proposing the toast of "The Royal College of Veterinary Surgeons," said he could not help thinking that in calling upon a layman to propose the toast the President ought to have asked someone who had the Abrahamic quality of being rich in flocks and herds—(laughter)—instead of which he, as representing a local authority enforcing the administration of the Diseases of Animals Act, had been selected for the honour. He could say on that account that he thought all such local authorities were under a great debt of obligation to the College for the ability and character of the officers the College presented to it. There were in London several veterinary inspectors, and it was a requirement of the Diseases of Animals Act that they should be members of the College. Anyone with experience of animal diseases must agree that that was a very desirable and necessary qualification. (Hear, hear.) Some years ago the London County Council in its Inspectorate did not have officers entirely in its own service, but a few years ago it made a change, and required that its inspectors should be officers who were not associated with private practice, but who devoted the whole of their time to the interests of the London County Council. At least two of the officers who came over to the Council at that time were gentlemen who, in entering public service, gave up a very much richer private reward, and he thought in estimating the value of the officers that came from the College that quality of self sacrifice was a very great asset. (Hear, hear.) The services rendered by those gentlemen to London had been very considerable indeed. One of the most serious diseases dealt with in London was a disease which affected the horse, and in a very long number of years a large number of horses had been destroyed by the local authority. The number of cases where the inspectors, he did not say made a mistake, but where on post-mortem they were unable to sustain their diagnosis had been considerably less than twenty—(cheers)—which was a very high testimonial to the skill and ability with which the members of the College were endowed before they entered the service of the L.C.C. (Hear, hear.) It was well known that a fierce light beat upon a crown, and there was sufficient talent amongst the veterinary surgeons in practice in London to pass under a very close observation the work of the L.C.C. inspectors. They were acting on behalf of their own clients, and it was pretty evident that if there was the slightest possibility of any mistake being made by the Council's officers they, in the interests of their clients, would be the first to detect it. That the inspectors have successfully survived this scrutiny was an additional tribute to the ability of the members of the College who served the L.C.C. (Hear, hear.) In connection with the work under the Glanders Order there was a special matter he desired to

mention because the present was essentially a professional gathering. Some months ago, when the London General Omnibus Company determined to put its horses under the hammer, the Council felt a very serious problem would arise if all those horses passed out into private stables and there was any possibility of taint of glanders existing amongst them, because it would have seriously retarded the efforts of the Council in putting an end to the disease. Mr. Hunting—(cheers)—accordingly saw Mr. Duff, the Managing Director of the L.G.O.C., an exceedingly keen and able man of business, and suggested that the whole of the horses should be malleined before they were sent to the auctioneer. After consultation with his own professional advisers, Mr. Duff agreed to submit the whole of the Company's horses to the mallein test, and he believed that out of about 7,000 that had been malleined up to the present time not more than 10 or 15 had had to be condemned. (Cheers.) That was another tribute to the ability of the gentlemen who had passed through the College, and who had served one of the largest omnibus undertakings in the whole world.

With regard to the future, there was no doubt that although very considerable advance had been made in the suppression of animal disease, there was still room for the exercise of the abilities of the members of the veterinary profession. One matter of very great alarm to the veterinary world was the recurrence of foot-and-mouth disease in several parts of the country. There were many directions in which the members of the College could serve the public, and he sincerely hoped the public would make a larger employment of their services. (Hear, hear.) Many years ago Mr. Coleman, who was one of the earliest veterinarians to preside over the destinies of the College, spoke very strongly of the necessity for ventilation, cleansing, and matters of that kind in connection with the housing of animal life, and he thought the owners of stock would be well advised to call upon the profession for a larger service in such matters than they rendered at the present time. He hoped that the veterinary profession would be properly recognised in the future, and such recognition would only be for the advantage of animal life. He had much pleasure in proposing the toast of "The Royal College of Veterinary Surgeons," and to associate with it the name of Sir John McFadyean, who was endeared to all because of his abiding interest in everything that was for the good of the profession, and because of his great scientific attainments, of which the veterinary profession was so proud. (Cheers.)

The toast having been duly honoured,

Sir JOHN MCFADYEAN, in responding to the toast in the absence of his old friend and former pupil, Prof. Mettam, the President of the Royal College, said he wished he could begin his reply by saying that everything was well with the Royal College of Veterinary Surgeons. Truth, however, compelled him to admit that in some respects the condition of the Royal College was not as good as its earnest well-wishers might desire. He had to confess that the extensive introduction of motor traction, the advent of the motor omnibus and the motor cab, and electric traction had made rather serious inroads on the income of some members of the profession. Perhaps nowhere had such great inroads been made as in the incomes of those who happened to practise in London. (Hear, hear.) He wished he could say that the substitution of motor traction for the horse was at an end, but he was afraid that that, from the veterinary point of view, would be too optimistic a forecast. He expected that in the future fewer horses would probably be seen in London and more motor cabs. He was pleased to observe in coming to the dinner that, owing to the taxi-cab strike, the hansom horse was getting a little of his own back—(laughter)—but he was afraid, as Carlyle said about his wife's toothache, that

would not be permanent. (Laughter.) In spite of those somewhat depressing facts he took a more optimistic view of the future than some people did. He did not believe the day was at hand when it would be impossible for a veterinary surgeon to make a decent livelihood in veterinary practice—(hear, hear)—and he did not share the view that before very long there would be no veterinary surgeons except those who were engaged in the service of the Board of Agriculture or of the London County Council. If one believed the gloomy prognostications that were sometimes heard, at no very distant date there would not be a horse left in the country, except possibly in a cage at the Zoo, and no equine thing would be left to the care of the Royal College of Veterinary Surgeons except the skeleton of Hermit. (Laughter.) He supposed that nothing was more calculated to destroy the interest attaching to an after dinner speech than the introduction of statistics into it, but he had looked up some figures relating to the animal population of the country, and found that notwithstanding the displacement of horses by motor cars, motor omnibuses, and electric trams, there was still a large amount of raw material from which veterinary surgeons might draw fees. According to the information supplied by the Board of Agriculture, there were in the United Kingdom in 1910 two million horses used for agricultural purposes, not including those that drew vehicles in London and other large towns. In addition to that, there were no fewer than 11½ million cattle, 31 million sheep, and 3½ million swine. When one considered that there was not the least likelihood of that immense animal population seriously diminishing in the near future, he thought those present were entitled to take a hopeful view of the veterinary profession in the future. (Hear, hear.) His own opinion was that the future of the profession in this country, and the future of the R.C.V.S., was quite likely to be better than it had been in the past. Agriculture as well as veterinary science was supposed to be in a bad way—it always was in a bad way more or less. (Laughter.) It had occurred to him that if it got worse perhaps some Chancellor of the Exchequer might be induced to introduce a Bill to take over the veterinary treatment of farm animals. (Laughter.) With regard to the figures he had mentioned, if one divided the number of farm animals by the number of veterinary surgeons in practice at the present time in this country, each veterinary surgeon would have the care of 16,000 animals, and he was in the hopes that the profession would be allowed 6s. a head for them. (Laughter and Cheers.) In conclusion he thanked those present very heartily for the way in which they had received the toast. They could hardly have received it otherwise, because the majority of them were members of the Royal College. Speaking not only for himself but for all members of the R.C.V.S., he thought their thanks were very specially due to Mr. Ollis for the more than sympathetic way in which he had proposed the toast. (Hear, hear.) There was one part of that gentleman's speech, however, which he thought was slightly out of place, namely, the part in which he in a measure excused himself for having been called upon to propose the toast. If the toast was not to be proposed by a member of the profession there were very few people better qualified than Mr. Ollis to undertake it. (Hear, hear.) It was probably true, as he had stated, that he was not rich in flocks and herds, but he certainly possessed other qualifications which made it very agreeable that he should propose the toast. He doubted whether there was any layman who knew more about one important disease than Mr. Ollis did, namely, glanders. But the members of the profession had one very serious complaint to make against Mr. Ollis. Mr. Ollis had asked them to take credit to themselves for the great service done in the public interests in the help

they had rendered in exterminating various serious animal plagues. Foot-and-mouth disease had been exterminated, although it was true it came back occasionally. Pleuro-pneumonia, which was at one time a perpetual feast to many members of the veterinary profession had been exterminated, and Mr. Ollis had referred to the fact that glanders was being exterminated. His complaint against Mr. Ollis was that he had conspired with an esteemed member of the Society, Mr. Hunting, in concocting measures to bring about the extermination of glanders—(laughter)—and sorrowfully it had to be admitted that their efforts were likely to be crowned with success. (Laughter and Cheers.) Taking that with the inroads that electric traction had made on the incomes of veterinary surgeons it was calculated to make them feel more or less depressed. Before he sat down, therefore, he would like to ask Mr. Ollis to use his influence in not pushing the thing too far—(laughter)—veterinary surgeons could do with glanders in London for a little while yet—(laughter)—and if, as seemed likely, glanders eventually disappeared, they still had 16,000 animals each to fall back upon. (Laughter and Cheers.)

Mr. J. WILLETT, in proposing "The Health of the Past-President, Mr. W. S. Mulvey," said the toast was a very simple and pleasant one, because it was easy to eulogise such a thoroughly good fellow. When he was elected to the Chair twelve months ago the members expected that he would uphold the traditions of the office, and he was sure all present would agree with him that they had no reason to be disappointed. (Cheers.) In previous years the toast had been put down on the list as "The Late President," which was a very dismal way of describing a man who had just done his duty in the Chair. (Laughter.) The last thing the Fellows wished Mr. Mulvey to think was that he was placed on the shelf and of no further use; and he therefore asked them to drink the future health and happiness of Mr. Mulvey and his better half. (Cheers.)

Mr. W. S. MULVEY, in responding, thanked the Fellows for the kindly way in which they had received the toast, and for their great forbearance with him during the past year. His year of office had been an extremely pleasant one to him, and now they had expressed their satisfaction the memory of it would be still more pleasant to him. (Cheers.)

Mr. W. HUNTING, in proposing the toast of the evening, "The Ladies," said the present was the first time the Society had invited ladies to be present at the annual banquet, and he thought everyone present would say that the new departure had been a very great success. (Hear, hear.) He had moved round the room two or three times, not exactly eavesdropping, but to talk to various friends, and nearly all of them had given him information for the constitution of a speech. From one quarter he declined to accept any of the suggestions made, because they were coffee-room tales. (Laughter.) It was hardly necessary for him to point out to those degenerates that he had never been present at a banquet which was so light and gay, and at which there was a higher tone and a more graceful appearance than the present one. When the ladies were not present the ordinary conversation was what was colloquially called "shop" but on the present occasion he had missed all that sort of thing, and the conversation had been distinctly of a higher type. Before coming to the dinner he had asked himself why an old decrepit man like himself had been selected to propose a toast which was usually given to a young man, who distinguished himself by flippancy and was generally guided in his idea of the sex in general by his last melancholy experience. (laughter) Personally he suggested that such a man was not a reliable guide. When a man arrived at his (Mr. Hunting's) age he had generally obtained a pretty tolerable experi-

ence of the sex in various relations—mothers, sisters, wives, daughters, and sometimes mothers-in-law (laughter). He had an experience far in excess of that of the younger man, and as the Secretary was at all times an enthusiast, and very often a humourist, he fancied that was the reason he had been chosen to propose the toast. (Hear, hear.) There had been a great change in the relationship of the sexes in the last few years. Without going into the political question, he wished to point out that the days in which a woman was supposed to have her proper sphere either in the kitchen or in the nursery had gone by. Men now wanted a companion, — somebody who was not only privileged to make half their troubles, but to enjoy all their joys, and to join in a conversation upon any subject without flippancy (cheers). It used to be said that women could not take a position of equality with man because she was neither physically nor mentally his equal. Personally he rather disputed that contention, because in many cases the woman was physically equal to man. From the mental point of view, he remembered a little anecdote which showed that women were not deficient in that respect. A young man, who thought he would take a rise out of a speaker at a Suffragette meeting, interrupted with the question "Don't you wish you were a man?" and instantly came the retort. "Don't you wish you were?" (Laughter). In another case Mr. John Burns was stopped by a lady as he was going to a political meeting and asked, "When are you going to give us the vote?" "When you can behave yourself" the Member replied. "Was it your good behaviour got you into Parliament?" felicitously replied the Suffragette. (Laughter).

Mr. J. W. McINTOSH, in responding on behalf of the ladies, said he could not speak with anything like the same degree of experience as the proposer of the toast, whose admiration for the ladies everyone present knew to be of a very high order. (Cheers). He thought all who had heard Mr. Hunting would agree that advancing years had not lessened in the slightest degree his admiration for their beauty and his appreciation of their worth and graces. On the contrary:

"Time but the impression stronger makes,
As streams their channels deeper wear."

Of woman's worth poets had sung in sweetest strain, but Scotland's immortal bard, Robbie Burns, stood pre-eminent as the champion of the ladies. His love songs, unrivalled for purity of diction, for pathos and true poetic feeling, struck a responsive chord on the glowing anvil of the human heart; and it was in that spirit he wrote the lines:

"Her 'prentice han' she tried on man
And then she made the lasses O."

He yielded to no man, not even Mr. Hunting, in a genuine appreciation of the beauty, grace, and virtue of the ladies, and he was very proud to have the opportunity of thanking the Fellows on their behalf for the pleasant evening they had been good enough to afford them. They were delighted to be present: their delight could be seen shining from their peerless eyes. (Cheers). They were enjoying themselves thoroughly, enjoyment could be seen reflected in the blushes on their cheeks (Cheers), and the ladies hoped they would be asked again. Personally he saw no reason why the annual dinner should not be held twice yearly (Laughter), in order to have the ladies present. (Cheers). The only blot in the evening's entertainment was that there were too few ladies and too many bachelors present: he hoped the position would be reversed before they met again. (Hear, hear). On behalf of the ladies, he thanked the Fellows very cordially for the enthusiastic way in which the toast had been received, and he had been asked to convey to Mr. Hunting, in homed phrases, a special vote of thanks for the gracious way in which he had proposed the toast. (Cheers).

Prof. G. H. WOOLDRIDGE, in proposing the toast of "The Visitors," said there were two sauces above all others that added relish to a good dinner, namely, the ladies and visitors. When he was first asked to propose the toast he felt rather in a quandary, because he did not understand at the time whether the ladies were to be regarded as visitors or not, but he had been saved any qualms in that respect by the fact that they had had a toast to themselves. But, apart from that, he was quite convinced the ladies were not to be regarded as visitors, because he had been talking to a number of them that evening and found they already considered themselves members of the Society. (Laughter and cheers). While those present did not know all the visitors individually, they were very pleased indeed to have them present at the banquet. One or two of them had already spoken, and it was most gratifying to know the interest they took in the profession. He wished particularly to mention the brother of the President, who had come all the way from the north country to support the President at the dinner. He also wished to couple with the toast the name of Mr. Grimes, who was a member of the Thames Conservancy, a member of a considerable number of local bodies, and a Justice of the Peace; he was also a frequent visitor and one whom they were always most pleased to welcome.

Dr. FOREMAN and Mr. GRIMES briefly responded on behalf of the visitors, and the singing of "Auld Lang Syne" brought a most successful gathering to a close.

During the evening an excellent musical programme was rendered by a quartette consisting of Miss Annie Bartle (soprano), Miss Florence Veming (contralto), Mr. James Horncastle (tenor), and Mr. Stewart Gardner (bass).

HUGH A. MACCORMACK, Hon. Sec.

LIVERPOOL UNIVERSITY VETERINARY MEDICAL SOCIETY.

A general meeting was held at the University on Tuesday, Nov. 7th, at 3.30 p.m. Present: The President, J. T. SHARE-JONES, Esq., F.R.C.V.S., M.Sc., in the chair; and Messrs. J. B. WOISTENHOLME, G. H. LOCKE, T. S. ATKINSON, T. DOBIE, H. HOLROYD, J. P. HEYES, J. MAGUIRE, A. WALKER, W. J. FLETCHER, P. CARTER, E. J. BURDRED, H. E. ANNETT, A. RICHARDSON, and W. WOODS.

Apologies for non-attendance were received from Messrs. A. TAYLOR, E. FAULKNER, J. BALL, and H. SUMNER.

Before the ordinary business was commenced it was agreed, on the motion of the President, to place on record the meeting's deep regret at the death of the late Sir R. BOYCE—a past president of the Society—and a personal friend of many of the members, and to acknowledge its very high sense of appreciation of the valuable services rendered to this Society, and to the veterinary profession as a whole by Sir Robert Boyce, especially his progressive attitude towards the relations between the medical and veterinary profession.

It was further resolved that the Society express its sincerest regret at the death of the late Prof. W. OWEN WILLIAMS, late President of the R.C.V.S., and Member of the Council of the R.C.V.S. The meeting desired to record its high appreciation of the services rendered to the profession by the late Prof. Williams in his capacity of writer and teacher.

These resolutions were passed in silence, the members all standing.

Mr. FRANK WARBURTON, M.R.C.V.S., was unanimously elected a member of the Society.

A letter was received from Mr. Gofton intimating that Rule 8 of the N.V.A. had been altered to permit members of the medical profession who at that time were ordinary members of any existing veterinary society to become members of the N.V.A. The meeting agreed that the Society become affiliated to the N.V.A. on condition that the amount of the assessment payable to the general funds of the N.V.A. be based upon the number of those eligible for membership of that Association.

It was resolved that in future all pathological specimens sent under Section 2 of the regulations of the Society be addressed to Mr. D. C. Mattinson, F.R.C.V.S., The Veterinary Pathology Department, The University. Specimens sent under Section 3 to be addressed to Dr. Annett, Runcorn.

Agreed that the next meeting be held on Tuesday, Dec. 5, at 3.30 p.m., when a paper will be read by Mr. A. B. Mattinson, F.R.C.V.S.

The discussion of the Presidential address was then resumed, and opened by Mr. J. P. Heyes, F.R.C.V.S., who was supported by Messrs. Burdred, Walker, Fletcher, Atkinson, Wolstenholme, and Richardson.

Mr. J. P. HEYES: It has been customary for as long as I can remember for the Presidents of Veterinary Societies to commence their period of office by giving an address on some subject of general interest to the profession, often what may be termed a domestic affair. It is looked for by the members of every Society, but it is not usually discussed. No apology need be offered for departing from the time-honoured course on this occasion, since it was adopted at the meeting following the election of president last year, with such success that I think all will agree a continuance of the practice is justified.

Another reason why the precedent set last year should be followed is that the theme chosen on this occasion is probably more interesting to us at the present time than any that could have been fixed upon.

The veterinary surgeon and the public. Two important circumstances enter into the consideration of the subject. Firstly, the qualification possessed by members of our profession, and secondly the requirements of the public.

That our attainments are such as to make us of considerable economic value to the people is evidenced by our existence, and by the progress made since our professional career began. It is undeniable that up to the present we have so far fulfilled the requirements of the public as to have gained full confidence.

With the progress of medical science which has been made in recent years, our ideas of disease, its causes and the conditions favourable or otherwise to its development and course have been very materially modified. Our knowledge and experience in this respect has caused us to direct our attention more and more to the prevention of disease.

Preventive medicine has now become a very important branch of medical study. There seems from the very earliest historical times to have been an impression in the minds of human beings that disease was preventable and could be lulled into a condition of impotence by the agency of charms, etc. Visitations of disease were, and in fact have been until comparatively recent times, regarded as manifestations of the wrath of the supernatural.

Early in the Christian Era certain diseases however, were believed to be infectious, and what is still the soundest preventive measure was advocated, namely, Isolation. It was not until the advent of the microscope that preventive medicine began seriously to develop. The discovery by Pasteur in 1863 of the first microbe of disease marked the epoch of revolutionary changes in

the medical world. Uncertainty gave place to certainty, and doubt was dissipated by actual demonstration.

One has only to call to mind the heavy losses borne by farmers in this country from Cattle plague, Pleuropneumonia, and other infectious diseases of stock to realise the importance of preventive medicine from an economic standpoint. Even now, in spite of all the precautions taken, large sums of money are lost every year through disease which will undoubtedly become preventable.

The matter is a serious one for the agriculturist, but when one remembers that many of these infectious diseases are communicable man, and that by want of adequate measures the health and lives of human beings are endangered, it becomes imperative that the best efforts should be made. Public bodies on whom devolve the duty of providing means for safeguarding the welfare of the people have in some localities looked to the veterinarian for assistance. In most of the smaller towns one finds the chief sanitary inspector under the supervision of the medical officer entrusted with the duties which properly belonging to the veterinary surgeon, such as inspection of cattle, cowsheds, milkshops, milk, and meat.

My experience of members of the sister profession engaged in Public Health work is that they welcome our assistance, and frequently recommend that our services be obtained for these duties.

If we compare our ways of dealing with the inspection of meat in this country with those which obtain on the Continent, we can only marvel at the apathy of the most enlightened people of the world. A uniform system of dealing with the work should be enforced all over the country, and placed under the control of members of our profession.

I notice that you, Mr. President, recommend veterinary surgeons to seek positions on public bodies. I am entirely in agreement on this point. The work connected with county or local councils frequently occupies a large amount of time, and often handicaps a practitioner in his struggle for existence. The older members of our profession who are able to place much of their work with assistants, and have spare time would be very serviceable.

To be identified with politics is not an unmixed blessing though, and one often gives offence quite unconsciously to one's clients through that medium. It is a duty all the same which we owe to our profession and to the public, and I know of no man who from his training and experience is better fitted for doing good service for the public on governing bodies than a veterinary surgeon. Much may be done, too, for our profession and agriculture by obtaining favourable acquaintance with our Parliamentary representatives. Members of Parliament, when any matter arises which affects the welfare of our calling are, in my experience, very thankful for information.

Training of the V.S. I wish to subscribe my approbation to the sentiments expressed by you, sir, respecting the need for better training on the part of our students. This is more particularly indicated in the case of men who aspire to Public Health appointments. The demand which will be made for veterinary surgeons to fill such posts will depend very largely on the qualifications of the men the profession has to offer. It is therefore incumbent upon us to recognise our own weaknesses and apply the proper remedies.

Already special courses of instruction in subjects which will assist our members in satisfactorily filling these positions have been instituted in connection with our schools, but I am afraid the time allowed is all too short for the work that ought to be accomplished.

In this age of specialisation we must keep pace with the times and arm our candidates with qualifications of indisputable value in the class of work to which they

aspire. A more intimate association with the universities would appear to offer to us a prospect of better facilities for study and research and, as Mr. Share-Jones has said, would probably be a means of securing funds to enable us carry out necessary but unremunerative work.

Pupilage. There is one portion of the training of a veterinary surgeon which is too often omitted, unfortunately nowadays, and which you, sir, have not made reference to, I mean that preliminary course in practical work which was, and sometimes is now obtained by a student before proceeding to College and during the vacations.

In your address you speak of the tendency of modern times to teach subjects of utilitarian importance even when the mind of the student is being prepared for the more important work connected with the calling which he desires to follow. Surely no better means exists of acquiring a preparatory knowledge of the animals amongst which he has to labour, and of their more common affections than by the serving of two years with a practising veterinary surgeon between the ages of 16 and 18 years. Any smart lad can pass the preliminary educational examination at 16 years, and 18 years is quite young enough for him to proceed to College.

During this time his interest will be aroused in the work of the profession and he will learn quite a large amount of useful information. The instruction given during his college course will be far more intelligible to him, and understanding, he will commence to assimilate the teaching at once. It is not so with the student who has not had the advantage of a pupilage, coming straight from school, and having absolutely no previous knowledge of the subjects he has to study, it is often difficult for him, to follow his teachers and consequently he is placed at a great disadvantage and often gets behind with his work as a result. Even if he is a very smart pupil and passes through his collegiate course quickly, his position when he is qualified is an unenviable one. He has managed to satisfy his examiners, but searching though such a test may be in the subjects taken, it cannot embrace much of the year's work. The task which has to follow is a more difficult one, namely, that of satisfying the public, and I am afraid an expert who cannot show a greater knowledge than his clients in conditions of animals which the latter does understand cannot impress them favourably.

It is truly lamentable to see a man who possesses the diploma of the R.C.V.S. unable to give a horse a ball or describing the incisor teeth of a cow as unsound, because they are loose. These and many worse exhibitions of want of information of the more commonplace nature I have encountered in qualified men. Other things being equal, we must expect men who have had the advantage of such a course to come out on the top. Again the practitioner, if he is a conscientious man, looks upon his pupil as a kind of godson, and prepares the lad by drawing on his own experience for many of the pit-falls which are encountered in practice.

Mr. E. J. BURNDRED: Mr. President, Mr. Heyes, and Gentlemen,—I much regret that I was unable to be present at the meeting when Mr. Share-Jones delivered his presidential address to the Society, but I have read it with great interest, especially as it deals largely with a question which is of great interest to me, that is, our place in public health work. Our President says that in the near future the profession will be confronted with the question of modification, and if necessary, amplification of its educational curriculum to meet the increased requirements which will be demanded in connection with the great question of public health. Now I beg to take exception to this wording. I say most emphatically that it is necessary to amplify the curriculum; students do not get training which fits them for their public

health duties, and if that is so, how can we expect to be appointed to these positions. Does the average final year student, for instance, get practical training in the examination of cows for tuberculosis of the udder? I don't mean *so called* typical tuber udders; there are plenty of these which are very misleading; but udders showing abnormality, and which are *known* to be positive by the application of the biological test to the milk.

Another important point is with regard to meat inspection. I think that it would be to the advantage of embryo meat inspectors if their training in this branch was obtained on the spot. By this I mean that they should accompany the meat inspector and see his procedure, and not merely see the meat after it has been seized.

Some of us who are at present holding public health appointments are fortunate, inasmuch as we are assistants to men who have made their mark as Veterinary Officers of Health, and who act as our teachers did in the old days, as counsellors and friends, but my appeal is for the present and future students, who will be called upon to carry out their duties without such help.

I am sorry to see the signs of the times with regard to the institution of University degrees. It seems to me to be the thin end of the wedge, and what is more important, wholesale granting of degrees by different examining bodies will not tend to make for uniformity in meat inspection, etc.

I should like to tender my thanks to our President for bringing forward this important subject, and for allowing a discussion. I would suggest that this Society should send a resolution to the R.C.V.S. asking them to revise the curriculum so as to better equip the future members of our profession for the work which will be before them.

Mr. JNO. B. WOLSTENHOLME: I have previously indicated my opinion that our President has given us a very valuable paper to discuss. In the main I am in agreement with him, and think, with respect to the entrance examination, that it requires toning up.

To my mind, Mr. Heyes, in opening the discussion has laid too much stress on the advantage to our profession of serving on public bodies; duty of this description is one of citizenship, and its claims rank higher than those of a profession, or of an individual.

There can be little doubt that a change is coming over the duties which the veterinary surgeon is called upon to perform, and some re-adjustment of the curriculum may be necessary. It strikes me as being unfair to expect that every man, at the time he receives his diploma to practise, should be perfectly equipped and fully competent to fulfil every demand which may be made upon him.

Especially is that the case with respect to the Public Health Service; in my opinion no man should be considered fully qualified for this work until he had taken a special course for the purpose, which should include practical teaching, to be followed by an examination which should be thorough, and one in which public bodies should place reliance and confidence.

The possession of a Diploma of Public Health should be equally necessary for the surgeon, or veterinary surgeon, before entering upon Public Health work; further there ought to be some central body or council whose duty it was to ensure that no such diploma was granted unless a definite standard of efficiency had been attained in the prescribed subjects. In other words there should be a State standard for a pass, wherever the diploma might issue from.

I am particularly pleased that certain degrees in veterinary science are now obtainable, and hope that our profession may be able to take its part in elucidating some of the many problems which medicine, in the

largest sense of that word, is putting forward for solution.

Mr. FLETCHER said he was glad of the opportunity of congratulating the President upon his excellent address, and also upon the fact that he was practising what he preached. As you may be aware Wales, as a memorial to the late King, have decided to institute a campaign against tuberculosis. It was my pleasure to attend one of the lectures held for that purpose. The lecturer was Mr. Share-Jones, the lecture most interesting and instructive. The Mayor of the Borough, a medical man, told me he considered it most enlightening, and he was sure the public had no idea that inspectorships were given to plumbers and tramcar conductors, that it was absurd and a waste of money for them to be placed in such positions with the necessary important duties to be performed. His Worship, the Mayor, also seemed very much impressed with the amount of good—from a public point of view—that must ensue when people were shown by the lecturer and limelight slides in a simple way the great danger they ran if their food supply was not properly inspected. For my own part I felt convinced our President was at the same time doing the veterinary profession good by demonstrating that we were capable, by our special training, of carrying out these duties. For this and for your Presidential address I beg to thank you.

The PRESIDENT expressed his thanks for the kind appreciation of his address. He felt particularly grateful to Mr. Fletcher for his reference to the public work which, with a few others, he was engaged in on behalf of his countrymen. They were engaged in that work not as medical men or veterinary surgeons, but as members of a community stimulated with one desire—to help the afflicted and protect the weak. He had some reasons to know that the work was appreciated by the public, and if incidentally it was proving of some assistance in enhancing the value of our profession in the public eye, then he was all the more pleased.

There was little for him to reply to, since the criticism of his address generally was constructive rather than destructive, and he was in the happy position of finding himself in almost complete accord with those who had spoken. It was commonly more difficult to adduce evidence in supporting a point than in opposition to it.

He agreed with Mr. Burndred and Mr. Heyes that there was need for a much more comprehensive training in the subject of meat and milk inspection. He had said so in his address. Meat inspection as practised in this country was just to no one. He did not think a guarantee should be required from the farmer or the butcher. The public should secure a general guarantee through their elected representatives or public bodies in the form of a general system of inspection with compensation provided out of the public funds. Of course there would be evasions. There were people who endeavoured to evade every law. But speaking generally, compensation out of the public funds would tend to diminish evasions rather than foster them, and would be equitable to farmer and butcher. His opinion was that, so far as being a means of eradicating tuberculosis for instance, the money which was being spent on meat inspection in this country might just as well be thrown into the gutter.

Mr. Heyes had raised the much discussed question of pupilage, which was not mentioned in his address. Whilst supporting the system of seeing practice with a veterinary surgeon, he (the President) was in direct opposition to Mr. Heyes when any system was advocated which would compel the son of a farmer who had lived his whole life on a farm to undergo exactly the same pupilage prior to entering a school as, for instance, the son of a draper who had no knowledge of the normal

conditions of animal life. Moreover, to require the boy of the latter type to spend two years with a V.S. before entering a school was, in his opinion, psychologically unsound.

The proper plan for such a pupil was at first on a farm, in order that he may be able to appreciate normal conditions before dealing with those which were abnormal. In this way his mind would undergo a rational development. There was another though perhaps less important aspect. If two years compulsory pupilage prior to entering a school were instituted, then taking five years as the time taken for an average student to pass his four professional examinations, this would mean that a boy at the outset would be called upon to enter on a seven years course. This would raise an economic difficulty which to the vast majority of parents and intending students would be absolutely prohibitive. Where was the return coming from for investing so much money and surrendering one-tenth of the life-span allotted to us? Whilst saying this he wished it to be understood that he yielded to no man in his desire to see the professional qualifications of their students as high as it was possible to make them, so far, of course, as was consistent with what was practicable. The previous home training, preliminary studies and financial resources of our students were so diverse that a general rule could not be formulated on an equitable basis, and it should remain as it hitherto was, a matter for the individual.

With regard to the University degrees, and in reply to Mr. Burndred, he could only say that if these were only conferred upon those who already possessed the license to practice, then those who wished to retain the one portal system need have no fear. He had mentioned this in his address. He (the President) advocated the granting of University Degrees for the power which they would bring to the profession—both to those who held the degree and those who did not. The holders of the degrees would become part of the University, and we should have representation in those quarters where public funds were disbursed for educational purposes. The value of our professional stock would be enhanced in the eyes of the public.

Mr. Heyes agrees with me that the profession should have a greater representation on our public bodies. But I cannot agree that the primary object in seeking election should be to secure appointments for members of our profession, but rather to act as guides and advisers when matters appertaining to our work arise, and to take our part in public work generally. The appointments would follow as a natural sequence where such were logically ours.

I am sorry that time has compelled me to curtail this discussion, but shall be pleased to discuss some of these points with Mr. Heyes when he reads his paper.

SPECIMENS.

The PRESIDENT submitted two cystic ovaries which had been removed from the mare. The subject was one upon which he demonstrated the operation to his class. Each member of the class was permitted to explore the vagina before the incision was made. He then made the incision above the os, and after exploring the abdominal cavity himself, allowed each student to do likewise, ordinary precautions being taken. The ovaries were then removed, the vagina swabbed out, and the mare was doing well at Messrs. Sumner's, and might be exhibited at the next meeting. He mentioned the case to show that no one need fear attempting the operation providing ordinary precautions are taken.

Afterwards the members had tea together.

Parasitic Mange Prosecution at Loughton.

On Friday, 17th, at Epping Petty Sessions, before W. C. Waller, Esq., Chairman; F. Dent, A. W. Leech, C. W. Skinner, and H. Triggs, Esq.

Charles Lucas, of Loughton Hall Farm, Loughton, a foreman in the employ of Messrs. Pickford, was summoned for failing to give notice of a case of parasitic mange.

Mr. Freeman Barrett, barrister, instructed by Messrs. Beard, solicitors, was for the defence, and pleaded not guilty.

Charles Fry, of Loughton, an inspector under the Diseases of Animals Act, said: I produce a copy of the Essex Parasitic Mange Order, 1909. About 2.30 p.m. on Nov. 1st, in company with Veterinary Inspector Howard, I visited Loughton Hall Farm, in the occupation of Messrs. Pickford, Ltd. I saw the defendant, Charles Lucas, and I said "We want to have a look at your horses." He said, "Very well, come this way." In No. 38 Box we found a chestnut gelding, No. 4767, branded on the off fore foot, which was suffering from skin disease, on the legs, hocks, thighs, and under the breast. Mr. Howard took portions of the hair and scurf from the animal, and on the 2nd Nov. he certified that it was affected with parasitic mange. On Nov. 3rd I went to the farm again. I saw the defendant, who is the foreman in charge there. He said that the horse came from Bearson's Depot, on Sept. 14th suffering from grease, and he had since been treating it for leg mite which he understood did not come in the Parasitic Mange Order. The other horses on the farm were examined by the veterinary inspector and found to be free from mange.

Mr. F. Dent, J.P.: The charge is that they ought to have known it was parasitic mange?—Witness: They ought to have notified the police.

In cross-examination by Mr. Freeman Barrett, witness said he knew defendant as an honest, straightforward man.

When he said he thought it was suffering from leg mite you believed it?—I did, to a certain extent. The leg mite is very seldom found high.

Your evidence is the lower hock was affected, the legs, that is to say the extremities of the body?—That is where it showed.

That is where the leg mite shows?—So I understand, below the knee or hock.

In bad cases extending to the uppers?—Yes.

You have known the foreman some time?—Yes.

He has given advice you wanted and helped you in every way?—Yes.

You don't doubt he is a truthful man?—No.

You have no doubt when the man said it was suffering from grease and leg mite he said what he believed to be true?—Yes, I think that is true. I pointed out to him a little scurf.

You have more knowledge than he has?—I think not. He meets with hundreds of horses.

The man told you he was treating the horse because it was suffering from grease and leg mite?—Yes.

Do you know of your own experience it was not symbiotic mange, which is not included in the Order?—If he had taken reasonable precautions he would have found it was not leg mite.

Mr. Barrett: I draw your Worship's attention to the three kinds of mange symbiotes or leg mite are speci-

ally excluded by the orders. The man told the Inspector he was treating for leg mite which is not included in the order, and if he was doing that honestly he did not evade the order. The point is did the man make an honest mistake? It is a large farm isn't it?—Yes.

You know Pickford's and Company?—Yes.

You know they own thousands of horses?—I should say so.

This is what they call their Sanatorium or Rest Farm?—Yes.

Horses affected in London are sent down there, and this was one of them?—Yes.

Did you examine the whole of the horses on the farm? How many were there in all?—81 in all.

Of all the number you only found two regarded as suspicious?—Yes, one a roan gelding, and one a chestnut.

Mr. Howard is examining veterinary surgeon. Did he examine those?—Yes, one, I don't know what it was suffering from—one was found afterwards not to be suffering with the mange.

But to be affected with ringworm?—I don't know about that.

The horse you say found to be suffering with mange was not much affected?—Yes on the legs.

The whole body was not covered?—When I visited on the 9th it was apparently rubbing its hind-quarters.

You examined 81 horses and found 2 suspicious. Don't you think this an excellent result?—Yes.

It shows care was exercised?—I must say he is a very careful man.

Mr. Howard had to put it under a microscope before saying yes or no?—Yes, but Lucas could have done the same.

He would not do that if he thought it was leg-mite would he?—You have been to the farm on many occasions; how many in the last two years?—A dozen.

Have you seen everything on the farm?—Oh, yes, there was no obstacle at all.

And nothing to complain of?—Last March, two cases, and he was officially cautioned. I was directed by the Clerk of the County Council.

You did not bring them here?—No.

Percy S. Howard, F.R.C.V.S., a Veterinary Inspector under the Essex County Council, said: On the afternoon of November 1 I visited Loughton Hill Farm in the occupation of Messrs. Pickford, and saw a chestnut gelding there with skin disease principally affecting the inside of the thighs. I took scrapings of the scurf patches in the position I have mentioned and I found the parasites of psoroptic mange microscopically, I certified the disease to be parasitic mange.

Cross-examined by Mr. Barrett: I want to ask you, there are three kinds of mange, and you agree that symbiotic mange is not included?—Exactly.

You found the inside of the thighs affected?—Yes.

And the hocks and the region of the hocks?—Not below the hocks.

I understood you took scrapings from the legs?—From the upper parts inside the thigh.

Did you find the legs affected?—Not so much as the thighs.

Were the legs affected?—They might have been slightly.

But psoroptes affect more principally the lower part of the body and upper skin surface?—They may.

This book says that symbiotes affect the upper skin. Therefore, whatever the nature of the parasite, don't you think a man with limited knowledge would suspect symbiotic and not psoroptic mange?—A man of his knowledge would not appreciate it—I mean would not differentiate.

Mr. F. Dent, J.P.: We want to know what a man with practical knowledge might reasonably be expected to suspect.

Mr. Barrett: Exactly. I put it to witness in this way Would a man of Lucas' standing understand the difference between the different parasites, or suspect them?—He would not be able to distinguish. He would know the horse had skin disease, and might know he had mange, but would not know what variety.

I suggest when he said the leg mite he would mean the excluded mite—the symbiotic mite?—No doubt he did mean it.

Therefore, unless he could see what was actually improved he believed he was treating something excluded from the Order?—Quite possibly.

Would you mind looking at this, it is a beautiful specimen, isn't it? (Specimen handed to witness).

Witness: I think it is symbiotes.

Mr. Barrett: I think you are absolutely wrong. What is that?—That is psoroptes.

You thought this was symbiotes; that is the excluded one. This is a criminal prosecution, you know.

Witness: It might be symbiotes.

Can you tell me what this is. It is a lovely specimen?—It resembles a symbiotes.

You did not make up your mind on the first visit to the farm in this case?—No.

Mr. Dent, J.P.: This is very interesting, but it does not seem to bear directly on the point whether they ought to have suspected.

Mr. Barrett: I understand you, but it is very important, as it may shorten the case very much.

To witness: The neighbouring horse was suffering from ringworm, wasn't it?—I did not find any parasites on that one.

Would you go further and say it was ringworm?—I would not say that.

Lucas was not a horsekeeper?—No, sir.

You went on the 1st Nov. and were not able to say definitely whether it was mange or not?—Well, it was a case one would suspect of mange.

Mange is a highly dangerous disease. If he did his duty, he would treat it in the interests of his firm. Had any dressings been applied as far as you know?—I should think they might have been.

It would be to the interest of the firm to discover mange at the earliest possible moment?—Yes.

Would you, as a veterinary surgeon, knowing the difficulties attending the diagnosis of mange, expect a man in Lucas' position to reasonably have known of the mange?—I think so, because it is such a common disease amongst horses.

And the horse was only slightly affected, whatever it may have been?—Quite so.

There was one case in 81 horses; are you going to say he was to blame?—I never said he was.

Do you think he was?—It is a very difficult thing to express an opinion on. I don't think either way would be fair.

Mr. F. Dent, J.P.: The real practical question is, ought a man of his position and knowledge to have known. You say that the horse had been suffering from grease?—Yes.

Are you prepared to say a man in Lucas' position, with his practical knowledge, ought to have suspected parasitic mange?—The man had so many horses. It is rather a complicated question.

It is quite a simple question. The point is: As a practical horsekeeper ought a man in Lucas' position to have suspected from what he saw that parasitic mange had developed in his horse at that stage?—It was obvious the horse had skin disease.

But notifiable disease. That is the point. I suppose a horse with grease would have some symptoms of skin disease?—Oh, it is a skin disease decidedly.

You have not answered my question. Ought a man in Lucas' position to have suspected it was a notifiable

disease!—The patch on the leg was large enough if he had noticed the horse. The point is whether in a number of horses he might overlook it.

Mr. Dent: I won't press the question if you can't answer.

This concluded the case for the prosecution, and Mr. Barrett suggested that he had no case to meet after the answers of the last witness.

The Bench consulted, after which the Chairman said: We think the case had better proceed.

Mr. Barrett: I ask you to take note that I submit from the evidence there can be no conviction. Mr. Howard said the defendant, with a large number of horses, might overlook it. He cannot give an opinion one way or the other.

Mr. H. Triggs, J.P.: But he was treating the case. How could he overlook it?

Mr. Barrett: They are always doing that; it might be nothing.

The Chairman: In the opinion of the Bench there is some reason for the case to go on.

DEFENCE.

Prof. Harold Woodruff, M.R.C.V.S., Professor of Medicine at the Royal Veterinary College, and lecturer, inspected the specimen which Mr. Howard had placed under the microscope, and said it was undoubtedly psoroptes.

Mr. Barrett: If there were 85 horses and only one affected with the disease, could a man with Lucas' knowledge be reasonably expected to suspect psoroptes and sarcopes as distinct from symbiotes?—I should say the ordinary horsekeeper knows the leg mite. From what I saw I should say the horse was recovering from a parasite, and the man might well think it was leg mite or itching leg.

If the man said it was suffering from grease, and treated it for leg mite, is that what you would reasonably expect?—Yes.

Cross-examined by Inspector Fry: If defendant had sent a portion of the scraping to the veterinary surgeon, do you think it would have been found out?—Professor Woodruff: I think that would presume he suspected it. The usual situation of psoroptic mange is about the mane and tail, and I failed to detect any adhesion there, psorptic or sarcopic, and all the books say it affects the coarse hair. It is so in fact with psoroptes and rather a common situation with others; it may spread to other situations, but not commonly.

You heard my evidence—that the horse was rubbing its hind-quarters?—The horse may rub its tail when it has itching leg.

You would not find the leg mite about the body?—My contention was that with itching it might easily rub its hind-quarters. I took scrapings from several places and found no parasites at all. I admit the legs inside the thighs and hocks were much worse affected.

Whatever the condition, it more especially pointed to itching leg?—To a man of Lucas' standing, he would think it was itching leg and leg mite.

Mr. Dent, J.P.: Any more expert evidence?—Mr. Barrett: I have two more.

Mr. Dent, J.P.: I don't see that more expert evidence will take us further. The order states that anybody having in his possession a horse affected by parasitic mange shall give notice. We have had no evidence. You don't dispute the owners had in their possession a horse having parasitic mange.

Mr. Barrett: The order does not say a person "shall know" but "having known."

Mr. Dent: The other point is: You have a man in charge, not, of course, highly trained in microscopics but presumed to know the ordinary symptoms of diseases and the opportunity of referring, if he likes, to the veterinary surgeon for the farm. When would a

man in his position call the attention of the veterinary surgeon to the case?—Mr. Barrett: we would almost say this was a sanatorium and the veterinary surgeon was in attendance when required, and the man could consult him in matters affecting the condition of the horses.

Charles Lucas, the defendant, said: I was in charge of these horses. I was foreman. I knew my instructions, and the horses received good treatment from me. I treated the horse in question in the first case for leg mite. He had grease from the hocks downwards, and I treated him for leg mite only. That is the only dressing the horse received. Until Mr. Howard visited the farm I had no suspicion whatever of there being any other condition than leg mite.

Mr. Dent, J.P.: Was the treatment ordered by the veterinary surgeon?—In that case I used my own discretion, because it was a clear case of grease.

You were treating the horse entirely on your own responsibility?—Yes.

Was your attention called to grease by the veterinary surgeon?—I found it out myself.

You did not see at any rate anything to cause you to report the case to the veterinary surgeon?—I should have done so.

You did not in fact?—No. My strict orders are when anything occurs to a horse I am to report to them and they will come down.

You did not in fact report anything about this horse?

—No, because grease is common and in the position of farm bailiff I am supposed to understand it.

Mr. Dent, J.P.: But the horse in point of fact had developed parasitic mange.—I did not know that.

Cross-examined by Mr. Fry: How long have you been foreman in charge?—Roughly, about 3 years.

You have a large number of horses under you?—Something like 150.

How many in the course of the year, roughly?—I should say some thousands—different horses.

You treat them for all kinds of different diseases, and you have a very good knowledge of horses?—Not particularly. I take a farmer's view of horses. I was a farmer's son, and we had about six horses. That is the knowledge I have of them.

How many suspected cases have you reported to me?—None at all.

The Bench retired and on their return the Chairman said:

JUDGMENT.

In this case the Bench after very careful consideration had decided to convict. There is no doubt that the horse was affected with parasitic mange, and though we do not consider that there was any wilful concealment on the part of Lucas, the circumstances were such that his suspicions ought to have been aroused, and that having regard to the importance of stamping-out the disease he should at any rate have taken the opinion of the firm's veterinary surgeon.

Mr. Barrett: Will you permit me to say one thing on that judgment? There is no doubt you are right in coming to the conclusion that the man should have called the surgeon's attention, but having regard to what you have said, I ask you to consider that to my firm the question is very important, and of course, to avoid a conviction upon the firm or one of their servants is the crux of the whole thing. May I suggest that justice will be met by paying costs without the actual recording of a conviction.

The Chairman: We convict, and of course we wish that the public should understand that in these cases every possible precaution must be taken. I do not think we can escape the necessity of fining.

Mr. Barrett: I had hoped you would say that a conviction need not necessarily be recorded. Everybody in the district will know through the local papers that

it is an offence, and that we have to pay the costs. It will make no difference to the public.

The Chairman: I am afraid we cannot consider that, because of course the public must know, and the public goes very largely on the decisions in these cases. We have decided to fine you 40/-, and 4/- costs.

PARLIAMENTARY.

Sir Fleetwood Wilson, the Financial Member of the Governor-General's Council, some time ago warned the Legislative Council of India that, in view of the approaching diminution of income due to the loss of the opium revenue consequent upon the agreement with China, it was absolutely essential, if increased taxation were to be avoided, to ensure "greater sobriety" in expenditure. The Government proposed to make a beginning by suppressing certain central appointments created in order that the Governor-General in Council might have expert advice, and might through the officials holding these posts, exercise a certain amount of authority over the local governments by way of co-ordination and general supervision. The Financial Member had marked down for abolition at the earliest convenient moment seven or eight appointments, and among them were those of the Director-General of Archaeology, of the Inspectors-General of Forests, of Agriculture, and of the Civil Veterinary Department, that of the Sanitary Commissioner with the Government of India, and those of Inspectors-General of Cantonments and of Excise in Salt.

The Secretary of State for India, in the course of his reply to Lord Curzon in the House of Lords on Nov. 2nd, said that, in consultation with the India Council, he had agreed to the abolition of the offices of Director of Agriculture, Inspector-General of the Civil Veterinary Department, and Inspecting Officer of Cantonments, but that it had been decided that it was necessary to retain the Director-General of Archaeology. With regard to certain other offices a final decision was reserved, but in agreement with the India Council he had formed the opinion that it was desirable to retain the office of Sanitary Commissioner, while asking the Government of India to consider what the actual relations of the Sanitary Commissioner to the Director-General of the Indian Medical Service should be.

* * * * *

In the House of Lords,

Earl CURZON raised a debate on the question of the abolition of the offices of Director-General and Inspector-General in several Departments of the India administration, and asked the Secretary of State to explain the policy of the Government in this respect.

The SECRETARY OF STATE: With regard to the office of Inspector-General, Civil Veterinary Department, Lord Crewe said that he agreed with the Government of India that it should be abolished; the provincial departments had gained experience, of which they made full use, and there was a Central Board of Veterinary Science which dealt with the problems in which veterinary surgeons were interested. It was believed that this Board would be able to exercise all the functions hitherto performed by the Inspector-General.

IMPORTED MILK.

In the House of Commons,

Mr. STANIER (Shropshire, Newport, Opp.) asked the President of the Board of Trade whether he could state the amount of milk imported into this country from Europe during this year, and showing the amounts separate for each country.

Mr. BUXTON (Tower Hamlets, Poplar): The total imports of fresh milk from Europe during the first ten months of this year amounted to 8,065cwt., of which 5,464cwt. were imported from France and 2,601cwt.

from the Netherlands. In addition, 9,177cwt. of cream were imported from Europe, of which 6,726cwt. were imported from France, 1,618cwt. from the Netherlands, 798cwt. from Norway, and 35cwt. from various other countries. These figures are, of course, exclusive of the imports of condensed milk, pure produce, and milk otherwise preserved.

Mr. STANIER: Is this milk examined to see that it does not contain any disease or contamination?

Mr. BUXTON: If the hon gentleman will give me notice of the question I will explain exactly the regulations.

Acorn Poisoning.

At Skirwith, Penrith, during the last ten days, Mr. T. Walker, Home Farm, lost five yearlings; Mr. M. Howson, Primrose Bank, one cow and two yearling heifers; Mr. W. Mallinson, Staingills, one cow and two two year old heifers, and Mr. J. Davidson a two year old heifer. In addition several farmers have cattle suffering from the same cause. In the Kirkoswald district, Mr. J. Thompson, Fog Close, lost four cattle and a young Clydesdale horse, and Messrs. Thompson, Demesne, two calving heifers and two horses.

Mr. Rumney, Keld Farm, near Bolton, Appleby, has suffered great loss on his farm, alleged to be due to his stock eating acorns in the fields. Early in the week a pedigree cow sickened and died, and later a valuable pedigree Clydesdale mare succumbed. There was no post-mortem. It was thought that the animals had died through a surfeit of acorns.

At Scotby Farm, tenanted by Mrs. Irving, six cattle were found to be ill on Sunday morning. By the time Mr. J. G. Bell (Messrs. Carlisle, Bell and Son) arrived three of the cattle were dead. A fourth animal had since died. A post-mortem examination has shown that the animals had been eating a yew tree.

Milk Scarcity Committee—Ireland.

His Excellency the Lord Lieutenant has appointed a Committee to inquire into this scarcity, and report upon the causes of the deficiency, and also to inquire into and report upon the dangers of contamination and infection in the present milk supply. The members of the Committee are—Mr. P. J. O'Neill, J.P. (Chairman), Sir John Lentaigue, F.R.C.S.I., Mr. George A. Moorhead, F.R.C.S.I., Mr. Alec. Wilson, of Belvoir Park, Belfast, Mr. Dermot O'Brien, President of the Royal Hibernian Academy, Mr. John R. Campbell, B.Sc., Mr. Albert E. Mettam, B.Sc., M.R.C.V.S., Principal in the Royal Veterinary College of Ireland, Lady Everard, of Randlestown, Navan, and Miss Margaret McNeill.—*Farmers' Gazette*.

The Board of Agriculture have awarded Research Scholarships in Agricultural Science to the following gentlemen:—P. G. Bailey, B.A., J. Clayton, B.A., J. T. Edwards, M.R.C.V.S., E. T. Halnan, B.A., J. Hammond, B.A., J. A. Hanley, A.R.C.S., G. E. Johnson, M.Sc., C. G. P. Laidlaw, B.A., A. E. Lechmere, M.Sc., J. W. Lesley, B.A., A. Neville, B.Sc., and G. T. Spinks, B.A. These scholarships have been established in connection with the scheme for the promotion of scientific research in agriculture, for the purposes of which the Treasury have sanctioned a grant to the Board from the Development Fund. The scholarships, which are of the annual value of £150, and are tenable for three years, have been established in order to train promising students, under suitable supervision, with a view to their contributing to the development of agriculture, either by carrying out independent research, or by acting in an advisory capacity to agriculturists.

PRESENTATION.

A very pleasant little ceremony took place at the King's Head Hotel, Sheffield, on Tuesday evening, Nov. 21st. It took the form of a presentation of 10 volumes of recent veterinary works to Mr. A. W. Noel Pillers, late District Veterinary Surgeon to the Great Central Railway, who is leaving the town. Each work contains the following inscription:—To A. W. Noel Pillers, F.R.C.V.S., as a token of esteem and recognition from his colleagues in Sheffield: Joseph Abson, F.R.C.V.S.; W. G. Jones, F.R.C.V.S.; Wm. J. Young, F.R.C.V.S., D.V.S.M.; T. C. Fletcher, M.R.C.V.S.; Geo. Green, M.R.C.V.S.; H. R. Laycock, M.R.C.V.S.; Herbert Nixon, M.R.C.V.S.; S. Nixon, M.R.C.V.S.; W. H. Murgatroyd, M.R.C.V.S.; S. E. Sampson, M.R.C.V.S.; H. Thompson, M.R.C.V.S.; J. H. Yates, M.R.C.V.S.

The meeting was presided over by Mr. T. C. Fletcher, M.R.C.V.S.; and Mr. Joseph Abson, F.R.C.V.S., made the presentation. The latter, in a happy and well chosen speech, commented upon Mr. Pillers' ever willing desire to help his brother practitioners, and on his keenness in matters veterinary. He wished, on behalf of the donors, every success and good health in his new appointment. Remarks of a similar nature were expressed by Messrs. Herbert Thompson, M.R.C.V.S., and S. E. Sampson, M.R.C.V.S.

Mr. PILLERS, in returning thanks for the handsome present, said he had done nothing more than his duty, and was more indebted to the Sheffield V.S. for the hospitality which had been extended to him, than they were to him. He was sorry to have to leave, but the books he had just received would always be a happy reminder of his Sheffield colleagues.

Votes of thanks to the Chairman and Mr. H. R. Laycock, who had organised the presentation, closed a pleasant and well deserved send off.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*,

WAR OFFICE, WHITEHALL, Nov. 17.

SPECIAL RESERVE OF OFFICERS.

ARMY VETERINARY CORPS.

Stuart Kirby Jones to be Lieut. (on probation). Dated Nov. 18.

OBITUARY.

WILLIAM THOMAS SABIN, M.R.C.V.S., Invercargill, N.Z.
Graduated, Lond: April, 1870.

WALTER JAMES BEART, M.R.C.V.S., King's Lynn.
Graduated, Lond: May, 1862.

The death has just occurred at King's Lynn of Mr. Walter James Beart, M.R.C.V.S., veterinary surgeon to the King at Sandringham. Mr. Beart was 74 years of age, and was a nephew of the late Prof. James Beart Symonds, Principal of the Royal Veterinary College. From 1863 until the time of the death of the late King Edward he was His Majesty's veterinary surgeon at Sandringham, and was one of the oldest Royal warrant-holders in Norfolk. He took his degree very early in life, and at the age of 18 years served as a veterinary surgeon in the Crimea. He had a large practice, and was much respected and esteemed throughout Norfolk.

FIBROLYSIN—AN ENQUIRY.

Sir,

Can any of your readers give their experience of fibrolysin?

I have been using it on a pony mare which received a kick on the postero-lateral aspect of the near hock about ten weeks ago. The wound healed up all right, but the

hock remained very much enlarged. After blistering twice with no result, I injected fibrolysin five times, four times into gluteal region and once into neck. The injections were made every second day.

After the fourth injection the hip became swollen and painful, and still remained so. That is now ten days ago. The neck within 24 hours of the injection in that situation became very much swollen and painful, with a good deal of constitutional disturbance. The swellings are not now so large, but there is a good deal of pain and some stiffness of limb, otherwise the pony appears all right.

The injections were all made antiseptically, a 5 per cent. solution of carbolic acid was used both for syringe and skin, the fibrolysin was warmed before using.—Yours etc.,

ENQUIRER.

COST OF MOTORING FOR A V.S.

Dear Mr. Editor,

Mr. Taylor of Hayward's Heath, has sent you particulars of the expenses of his motor car. I enclose you a cutting from *The Peoples Journal* (published in Dundee) of 21st Oct. giving an analysis of the cost of running and maintaining the motor car of the Lord Provost of Glasgow. You will see the figures are taken from the municipal accounts of that city.—Yours truly,

S. V.

"We wonder when the Corporation of Glasgow resolved to supersede the horse-driven carriages by a superb motor car for the Lord Provost, and whether the cost of running and maintaining the car formed part of their deliberations as to the utility of the change. It is the first cost of a motor car that usually sticks most people from indulging, but it is apparent from the accounts of Glasgow's Common Good Fund that the upkeep of this new method of conveying Glasgow's honoured chief is to cost the citizens a "bonny penny."

Appended are the details of expenditure precisely as they appear in the accounts of Glasgow's Common Good Fund for the year.

LORD PROVOST'S MOTOR CAR.

Wages of chauffeur and assistant	£197 0 0
Outfits of chauffeur and assistant	42 12 6
Petrol, tyres, repairs, and sundries	753 8 8
Insurance—fire, theft, and accident	19 8 9
Depreciation of car, 20 per cent. on	
£903 15s. 6d.	180 15 1

Total £1193 5 0

Of this total £137 16s. 4d. was incurred during 1909 and 1910. The net total cost for the year thus amounted to £1055 8s. 9d. The value of the car is stated at £900. Accordingly it is taking considerably more to run the vehicle yearly than to purchase the car itself. The item £753 8s. 8d. for petrol, tyres, repairs and sundries is a staggerer, and adequately attests what an extraordinarily busy man the Lord Provost of Glasgow is."

HORSE V. MOTOR FOR VETERINARY WORK.

Sir,

As this subject is now under discussion, I should like to give facts concerning same. What a veterinary surgeon requires at least is a ten—twelve horse power twin cylinder two seater, with boot for drugs and instruments. The cost of running same, allowing for interest and depreciation, in fact all in, is 4½d. per mile. Cob with same equipment 2½d. per mile. Average speed, motor 18 miles per hour; cob 9 miles, slower but surer.

My object in writing this letter is to know whether a country veterinary surgeon of average ability can possibly run a motor of this description and live and pay his way. The accountant who is going through my affairs for income tax, absolutely declares that I am a philanthropist to my clients to the extent of £142 per annum.—Your faithfully,

Geo. Urton.

Epping, Essex. Nov. 14.

Royal Veterinary College, London.

(Founded 1791.)

Principal and Dean : Professor **SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.**

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities, etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.), which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts, and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 7th, and terminate on Friday, November 29th, 1912.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

Royal Veterinary College, Camden Town, N.W.

PRACTICES FOR DISPOSAL

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

HOME COUNTY. Receipts £350 to £400 per ann. Rent £35. Premium required £200.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SCOTLAND. Returning over £300 per annum. Expenses very low. Premium £120, or nearest offer.

YORKSHIRE. Receipts 1910 £332. Rent £19. Premium £300.

Telephone: No. 2, Belton.

Commonwealth of Australia

APPLICATIONS are invited for the position of Meat Inspector from qualified veterinary surgeons with practical experience and expert knowledge of meat inspection.

The officer chosen will be attached to the office of the High Commissioner for Australia. Salary £600 per ann. Applicants must state age, and forward copies of testimonials.

Applications to be addressed to the Official Secretary, Commonwealth Offices, 72 Victoria Street, Westminster, and will be received up to December 18th, 1911.

As Assistant or Locum

M.R.C.V.S., (1909), desires position as assistant or locum: good horseman, excellent references: Address, V.S., 39 Little Heath, Old Charlton, Kent.

Partner Wanted

WANTED a thoroughly reliable, practical, qualified married man as partner in high-class country practice. Full particulars in strict confidence on application. Only bonafide applicants will be entertained. Address, 1121 V.R., 20 Fulham Road, London, S.W.

Practice or Partnership

ADVERTISER, who has £1200 on hand, will be pleased to have particulars of practice or partnership for sale up to that amount, confidence respected, no intermediaries. Address, 2114 V.R., 20 Fulham Road, London, S.W.

Manager Wanted

COUNTRY branch, married preferred, experienced, standing castrator, good references. State age, and salary required. House free. Address, 1125 V.R., 20 Fulham Road, London, S.W.

For Disposal

GENUINE country practice, market town, Yorks. C.C. appointments. Receipts about £300, introduction. Must be sold, £50. Address, 1123 V.R. 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

As Assistant

DSTUDENT, abstainer, good address, tact and ability much practical experience; seeks assistantship, busy practice. Small salary and accommodation expected, Ride, drive. Numerous references as to ability and character. Greener, P.O., Ballsbridge, Dublin.

For Sale

MICROSCOPE new, in box, double nose piece and lenses, would suit 2nd or 3rd years student, cheap. Also new pair molar shears, with cover plate and chased screw-on handle, improved, cheap. Address, 1122 V.R., 20 Fulham Road, London, S.W.

As Assistant or Branch Manager

ADVERTISER, a thoroughly practical man, desires permanent situation. Many years experience, town and country, has managed branch, abstainer. Address, 4112 V.R., 20 Fulham Road, London, S.W.

As Locum, Manager or Assistant

MR.C.V.S. (36), desires position as locum, manager or assistant, best references. Address, M. C., Royal Vety. Coll., Camden Town, London, N.W.

To Veterinary Surgeons

MR.C.V.S. (36) recovering from serious illness, desires light work, e.g. attending yard cases, walking visits and dispensing. Small salary. Apply, A. A., Stewart, Solicitor, 205 Hope Street, Glasgow

Wanted

GOOD Practitioner as partner, to have early succession, in old established practice, market town in one of the best districts in the South of Scotland: average return about £400 per annum. Address, 4114 V.R., 20 Fulham Road, London, S.W.

Canine Nurse, Clerk, Dispenser

WIDOW of V.S., desires employment in either or all of these capacities. Address, 5311 V.R. 20 Fulham Road, London, S.W.

Partner Wanted

IN good practice, S. Wales. A good opening for a younger man who is a worker. Or would sell. Address, 4311 V.R., 20 Fulham Road, London, S.W.

As Assistant

ASSISTANT (1899), steady; will furnish references. Would act as locum. Address, 3117 V.R. 20 Fulham Road, London, S.W.

Practice

WANTED to purchase for cash, sound country practice returning about £1000 per ann., must bear strict investigation. Address, 3113 V.R., 20 Fulham Road, London, S.W.

As Locum

VETERINARY Surgeon, post graduate, offers his services as locum, any time between Dec. 1st and 21st. Excellent references. Address, G. A. Roberts, R.V. Coll. Camden Town, N.W.

Partnership

THOROUGHLY reliable, practical V.S., age 33, desires partnership, view to succession, or would buy practice or nucleus in a good hunting country. Address, 3109 V.R., 20 Fulham Road, London, S.W.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

Locum Tenens

MR.C.V.S., thoroughly used to country practice and holding testimonials as to ability and general character from many practitioners, is always open to engagement when not actually filling a post. Permanent Address, "Locum," 59 Gascony Avenue, London, N.W.

ROYAL (DICK) VETERINARY COLLEGE, Edinburgh,

Appeal for Funds towards New College Buildings and Equipment.

THE BOARD OF MANAGEMENT beg to draw the attention of the Public to this important National Scheme, involving an expenditure of about £50,000, and to solicit contributions to enable them to complete arrangements for the commencement of Building Operations at an early date—a Site at Summerhall, situated at the east end of the Meadows having been acquired for this purpose.

Subscriptions to the amount of £20,006 10s. have already been intimated. The Scotch Education Department has promised to contribute (up to the sum of nearly £25,000), an equivalent to the amount raised by subscriptions. The sum, therefore, now required to complete the Scheme is £5000.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1221.

DECEMBER 2, 1911.

VOL. XXIV.

RESEARCH SCHOLARSHIPS FOR VETERINARY SURGEONS

It is barely two months since Mr. Stockman, in his inaugural address at Camden Town, drew attention to the research scholarships which are now opening to our graduates. Few of his hearers, perhaps, imagined at the time how speedily a veterinary surgeon would profit by these new facilities. Last week we published a list of the recipients of the first twelve Scholarships in Agricultural Research awarded by the Board of Agriculture; and in that list appeared the name of Mr. J. T. Edwards, M.R.C.V.S.

The Board of Agriculture will award twelve more such scholarships annually for two years to come, each being tenable for three years, and of the annual value of £150. They are not intended either as a permanent source of income to those who gain them, or as a means of obtaining additional degrees. Their object is to enable men to "train seriously as investigators"—to afford promising graduates a maintenance during the period necessary for their development into specialists in research. The idea is no new one, for similar scholarships in many subjects have long been in vogue. What is new is that these are open to veterinary surgeons.

Mr. Edwards graduated last July, after a distinguished college career. That career, and doubtless the personal recommendations of his teachers in addition, have gained him his scholarship. Analogous scholarships have long been accessible to young medical graduates of the same calibre; and many a brilliant student has developed into a reliable investigator by their means. But hitherto a veterinarian desiring to advance in this direction has been obliged to do so at his own expense; and unless either possessed of private means or fortunate enough to obtain one of the very few paid positions—such as a professorship of anatomy—which carry exceptional facilities for study along with them, his progress has been practically barred. At last the Government has recognised the wisdom of facilitating veterinary research, and the scholarships just created are the first, but not the last, step towards it. The scholarships are only a part of an extensive scheme for the development of agricultural science, which includes the maintenance at certain institutions of workers upon special subjects, veterinary among the rest.

The pick of our young graduates have now far better chances than ever before. Something is to be done by the State to assist their higher scientific training; something, also, to utilise its results. Recognition of veterinary science by the State has come very slowly, but it seems to be here at last.

LINGUATULA LARVÆ AND PERITONITIS.

By A. S. LEESE, L.C.V.D.,
Investigating Camel Diseases.

Through the kindness of Mr. Leese, we are able to reprint the following article from *The Journal of Tropical Veterinary Science*, Vol. VI., Part III.

Colin found larvæ of *Linguatula tænioides* in the mesentery of a dromedary many years ago.

In the course of my work with Indian camels in which for some time at first I did not find these larvæ, it was found that they have a predilection for a certain group of glands which were only occasionally examined, the group draining the cæcum and colon.

Since this was noted, the parasites have been found in nearly half the cases in which they were searched for, which shows that they are exceedingly common in this situation in Punjab camels; more rarely they can also be found in the lymph glands of the small intestine.

The affected glands are generally inflamed in patches and show little cavities in which the parasites have been encysted; the inflammation is most marked when larvæ are abundant.

In September, 1909, when in Montgomery district a number of good-conditioned camels were found to be dying from a peritonitis which was characterised by the formation of a mass of new inflammatory tissue around and between the coils of the colon which led to strangulation of the bowel, and sometimes rupture of the bowel.

The usual duration of this disease was 10 or 12 days.

The disease did not appear to be contagious since the cases occurred independently; the blood, when inoculated into a camel and some other animals, was found innocuous; neither foreign body nor volvulus were present, nor any lesion other than peritonitis except the gangrene and inflammation of the intestine for a short distance in front of the point of strangulation. Only one post-mortem (under very adverse conditions) was carried out by me, and I failed to find any channel by which bacteria could have reached the peritoneum in the first place; but it must be admitted that the lymph glands of the intestines were hardly examined at all. An assistant made several further post-mortems and brought specimens of the lesions with him to headquarters, whereby it was found that the lesion was similar in all the cases; but the lymph glands of the part were unfortunately forgotten.

Later, when *Linguatula* larvæ had been found common in the camel in the lymph glands of the cæcum and colon, it occurred to me that this peri-

tonitis might be due to the irritation caused by the wanderings of *Linguatula* larvæ after leaving the lymph glands; but the inflammatory new tissue had been thoroughly searched for small parasites without success, and it is hardly possible that free larvæ in it could have been missed.

Although I visited Montgomery again in September, 1910, I was unable to get hold of another case of this peritonitis, although I found *Linguatula* larvæ there in one camel out of three which had died of other diseases.

In October, however, a case of acute peritonitis occurred at Sohawa which seemed to shed some light on the matter. The camel was an old one, in good condition, but affected with surra, and destined for experimental treatment; he arrived on 4th October, and was then kept for observation of blood and temperature until 17th, when the first symptoms of peritonitis were noticed. Up to this date he had been grazed and fed along with 20 others under ideal conditions; the weather was good, and no reason for the onset of the disease could be discovered.

He died on 20th after only 3½ days' illness, and on post-mortem peritonitis was the only lesion; it was acute (with no time for formation of inflammatory fibrous tissue) and diffused, though the lesions were most pronounced in the mesenteries of colon, rectum and small intestine, and in the peritoneal covering of colon.

The glands of the cæcum and colon and many of those of the small intestine were swollen and intensely inflamed, contained large numbers of *Linguatula tænioides* larvæ, and were full of cavities which had been occupied by the parasites, many of these cavities opening on the outer surface of the glands. There was no enteritis, nor was any other channel for infection found, nor was the camel harbouring *Schistosomum* (a parasite of this genus has lately been found fairly common in the camel).

No free larvæ could be found in the peritoneal cavity, showing that the peritonitis could hardly have been caused by the mechanical irritation of *Linguatula* larvæ wandering free in the peritoneal cavity; but the functional destruction of the lymph glands due to the large number of larvæ appears to have allowed the access of bacteria from the intestine to the peritoneum, the larvæ of *Linguatula tænioides* thus acting in an indirect manner in bringing about the peritonitis.

Had this camel not died so quickly of toxin absorption, it is possible that the productive inflammation characteristic of the peritonitis seen in Montgomery would have eventually taken place.

The fairly frequent occurrence of peritonitis in camels in good condition without external cause, the frequency with which *Linguatula* larvæ are met with in partially destroyed or inflamed lymph glands of the intestines, and the Sahawa case above described indicate that *Linguatula* larvæ may be found to be of considerable practical importance on further investigation of the diseases of camels and possibly also of other animals.

INHALATION OF SMOKE CAUSING DEATH.

By HENRY TAYLOR, F.R.C.V.S., Haywards Heath.

A few weeks ago I was asked to see a horse belonging to an orchid and carnation grower. The animal was perfectly all right one Saturday morning, and was sent to work in the garden in close proximity to a heap of burning refuse from which were evolved dense volumes of a particularly pungent smoke. Two men were working with the horse for about two hours under those conditions, and they were taken with sickness in the afternoon with violent retching and pain in the chest, but this had passed away by next morning. On the Monday morning the horse, when I saw him, presented all the symptoms of a bad attack of pneumonia, but a noticeable symptom was a curious bright red or scarlet appearance of the mucous membrane of the nostrils, a condition which I remembered is said to occur in poisoning by meth. hæmoglobin. The heart was beating tumultuously at the rate of 85 to the minute. The animal refused all food, got rapidly worse, and died during the course of the night of the following day. The day before he died there was an extremely fetid diarrhœa.

ABSTRACTS.

AN UNDESCRIBED ORGANISM SIMULATING BLACK-QUARTER IN ITS PATHOGENICITY.

Major F. G. H. Baldrey describes (*Journal of Tropical Veterinary Science*, Vol. VI., Part III.) a hitherto undescribed organism which may prove, in India at least, to be of considerable importance.

It is a di-morphic cocco-bacillus, appearing in the form of short rods which divide in coccoid chains. It is non-sporulating and Gram negative. In many of its characters it closely resembles an organism already described by Ludwig Lauen as having caused considerable loss in laboratory animals. Baldrey gives a table of comparison between the two organisms, from which it appears that, though similar, they are not identical, as some points of difference can be observed. Both organisms are pathogenic to guinea-pigs, rabbits, and mice; and Baldrey's microbe is also pathogenic to cattle and sheep.

Injected subcutaneously, Baldrey's organism usually causes local pain, soreness, and swelling. Injected intra-peritoneally, it causes congestion of the mesentery. In either case the tissues around the seat of inoculation present an appearance closely resembling that of quarter-ill, but the characteristic odour of that disease is absent. Death is common, after a course which may be acute, lasting from 1 to 4 days, or more or less chronic, extending over 10 to 20 days. Recovery may, however, occur; and occasionally subcutaneous inoculation gives negative results.

Death seems to occur from toxæmia. When inoculated subcutaneously, the organism can be

recovered from the local lesion, but not from the general circulation. When inoculated intra-peritoneally, it can be isolated by cultural methods from the blood of the heart, but the organisms are so few that they are undemonstrable by microscopic examination of the blood.

The organism was first found in a sheep which, in the course of some experimental work at Bareilly, died after being vaccinated for anthrax. At first it was thought that death was due to anthrax, but closer examination proved it to have been caused by this new organism. Sheep seem much more susceptible to the organism, and much more liable to acute toxæmia from it, than cattle.

In cattle especially, the effect of subcutaneous inoculation tends to become chronic, forming a swelling which is hard and painful at first, and, if situated in the leg, causes marked lameness. This symptom is of importance on account of its possible confusion with quarter-ill. Of late, cases have been reported of animals dying of intercurrent disease after inoculation with "blacklegoids," which deaths were supposed to be from quarter-ill. Baldrey thinks it very likely that they were really due to this new microbe, and emphasises the importance of careful investigation of all cases reported as quarter-ill, especially after the use of "blacklegoids."

Further experiments upon the organism and its toxin have been undertaken by Dr. Hartley, and are still in progress. Some have been in the direction of protective vaccination, which does not seem to be very successful in this disease; and the preparation of an anti-toxic serum appears more hopeful. This latter is now being worked upon, and will form the subject of a further report.

ACTINOMYCOSIS OF THE RECTUM IN THE HORSE.

Markus records (*Tydschrift voor Veeartsenijkunde*) the following case. The subject was a cross-bred Oldenburg mare, four years old, which for some time had been losing condition and showing difficulty in defæcation. Rectal exploration had revealed the existence of a marked engorgement of the roof of the rectum. The mare was put to grass with a view to rendering defæcation more easy.

However, the loss of condition became more accentuated, while the rectal stenosis increased from day to day. At the end of four months from the onset of the first symptoms, defæcation became impossible, and the animal was destroyed.

The post-mortem examination resulted as follows. In the rectal wall, about four inches in front of the anus, was a neoplasm of about from nine and a half to ten inches in diameter. Its surface was flat towards the lumen of the gut, and convex towards its exterior. Its greatest thickness was about four and a half inches. The mucous membrane, which covered it completely, was almost normal; but at some points the tumour showed a diminution of consistence, and at these places the mucous membrane was in some degree infiltrated with neoplastic tissue. Beneath the mucous membrane was a tissue of slight consistence, yellowish-grey superficially, but red-brown in its deep layers. In some

places a meshwork was found, filled with creamy, inodorous, yellowish pus.

Microscopical examination showed that the neoplasm was actinomycotic in nature. The actinomyces were surrounded by a large quantity of pus cells, amongst which, especially in the superficial portion, fibroblasts were found. In the microscopic preparations, the actinomyces were seen in the form of fine filaments, sometimes granular, and collected in a network. The spores were abundant in the meshes which were formed amongst these filaments.

The corresponding lymphatic glands were engorged and lardaceous, but did not show any specific lesion.

This observation is of interest from the species of animal in which the lesion was found and the special localisation of the disease. Huttyra and Marek, and also Friedberger and Fröhner, while mentioning the possibility of actinomycosis affecting the horse, say nothing of its rectal localisation. Kitt does not even name the horse among the animals capable of contracting actinomycosis.

Markus himself insists upon the great rarity of equine actinomycosis; for, during a period of five years, the anatomo-pathological institute with which he is connected has only received one case of this nature, while a dozen cases of bovine actinomycosis have been encountered during the same period in the same establishment. Equine botryomycosis, on the other hand, is much more frequent than equine actinomycosis, for eleven cases have been seen at the Institute. Five of these were in the spermatic cord, two in the skin of the breast, two in the skin of a hernial sac which had been operated upon, one on the perineum, one on the shoulder, and one in the liver and diaphragm.

In the case reported above it is probable that the infection of the rectal wall had been produced by an awn of rye or wheat contaminated by actinomycosis. The author suggests the possibility of a diagnosis during life by curettage of the neoplasm and microscopical examination of the fragments of tissue collected by the curette.—(*Annales de Méd. Vét.*)

W. R. C.

ORDER OF THE BOARD OF AGRICULTURE AND FISHERIES. (DATED NOVEMBER 22, 1911).

PARASITIC MANGE ORDER OF 1911.

The Board of Agriculture and Fisheries, by virtue and in exercise of the powers vested in them under the Diseases of Animals Acts, 1894 to 1911, and of every other power enabling them in this behalf, do order, and it is hereby ordered, as follows:

Definition of Parasitic Mange.

1. The expression "parasitic mange" in this Order means sarcoptic mange or psoroptic mange in a horse, ass, or mule.

Separation of Diseased and Suspected Animals and Notice of Disease.

2.—(1) Every person having in his possession or under his charge a horse, ass, or mule affected with or

suspected of parasitic mange shall (a) as far as practicable keep that animal separate from horses, asses, and mules not so affected or suspected; and (b) with all practicable speed give notice of the fact of the horse, ass, or mule being so affected or suspected to a constable of the police force for the area wherein the horse, ass or mule so affected or suspected is, who shall forthwith give information of the receipt of the notice to an Inspector of the Local Authority.

(2) In the administrative county of London (including the City of London) the notice may be given to an Inspector of the Local Authority.

(3) An Inspector of the Local Authority who receives information of the existence or supposed existence of parasitic mange shall forthwith report the fact to the Local Authority.

Notification of Disease by Veterinary Surgeons.

(3) The Animals (Notification of Disease) Order of 1910 shall be read and have effect as if parasitic mange were included in the list of diseases to which that Order applies, and as if notice of the existence or suspected existence of parasitic mange were required by that Order to be given by a Veterinary Surgeon or Veterinary Practitioner to an Inspector of the Local Authority.

Veterinary Inquiry by Local Authority as to existence of Parasitic Mange.

4.—(1) The Local Authority on receiving information of the existence, or supposed existence, of parasitic mange shall forthwith cause inquiry to be instituted as to the correctness of such information with the assistance and advice of a Veterinary Inspector, or of a veterinary practitioner qualified according to the Act of 1894 to be a Veterinary Inspector.

(2) The owner and occupier of any premises on which there is a horse, ass, or mule affected with, or suspected of, parasitic mange, shall give all reasonable facilities for the enquiry by the Local Authority under this Article.

Detention and Treatment of Animals.

5.—(1) A Veterinary Inspector of the Local Authority may serve a notice (in the Form A set forth in the Schedule to this Order, or to the like effect) on the occupier of any stable, shed, field, or other premises in which there is a horse, ass, or mule which in his opinion is affected with parasitic mange, and thereupon the following restrictions shall take effect:

(i) The horse, ass, or mule so affected shall not be moved out of the stable, shed, field or other premises specified in the Notice, except with the written authority, and under the supervision, of an Inspector of the Local Authority, and only to some other place of detention or to a knacker's yard: and during the detention it shall from time to time, as often as may be necessary, be treated by the owner thereof with some dressing or other remedy for parasitic mange approved for that purpose by a Veterinary Inspector of the Local Authority or a Veterinary Surgeon or Veterinary Practitioner employed by the owner of the animal to examine it;

(ii) No other horse, ass, or mule shall be moved out of the stable, shed, field or other premises unless on each occasion immediately before the movement it is treated with some dressing or other remedy for parasitic mange approved for that purpose by a Veterinary Inspector of the Local Authority or a Veterinary Surgeon or Veterinary Practitioner employed by the owner of the animal to examine it;

(iii) No horse, ass, or mule shall be allowed by the owner or person in charge thereof to stray out of the stable, shed, field or other premises.

(2) A Notice under this Order shall remain in force until it is withdrawn by a Notice in writing served on

the occupier of the premises by an Inspector of the Local Authority.

(3) Where a Notice refers to two or more diseased animals the Notice may subsequently be altered so as to refer to one or more of such animals only.

(4) An Inspector shall with all practicable speed send a copy of any Notice served under this Article to the Local Authority and to the police officer in charge of the nearest police station of the District.

Cleansing and Disinfection.

6.—(1) Any place in which a horse, ass, or mule affected with, or suspected of, parasitic mange has been kept shall, if and when so required by an Inspector of the Local Authority, be cleansed and disinfected by, and at the expense of, the occupier of such place as follows:—

(a) The place shall be swept out, and the sweepings shall forthwith be well mixed with quicklime and be effectually removed from contact with horses, asses or mules; and

(b) The floor of the place and all other parts thereof with which such horse, ass, or mule has come in contact shall be thoroughly washed, or scrubbed, or scoured with water; then

(c) The same parts of the place shall, so far as is practicable, be disinfected in accordance with the subsequent provisions of this Article.

(d) In the case of a field or other place which is not capable of being so cleansed and disinfected, it shall be sufficient if such field or place be cleansed and disinfected as far as practicable and to the satisfaction of an Inspector of the Local Authority.

(2) Every utensil, manger, feeding-trough, pen, hurdle, harness, clothing, or other thing used for or about a horse, ass or mule affected with, or suspected of, parasitic mange shall, as soon as practicable after being so used, and before being used for any other horse, ass or mule, be cleansed by being thoroughly washed, or scrubbed, or scoured with water, and subsequently disinfected in accordance with the subsequent provisions of this Article, and such cleansing and disinfection shall be carried out by, and at the expense of, the owner of the thing.

(3) Every place or thing, or part thereof, required by this Article to be disinfected shall be thoroughly coated or washed with—

(a) a one per cent. (minimum) solution of chloride of lime containing not less than thirty per cent. of available chlorine; or

(b) a four per cent. (minimum) solution of carbolic acid (containing not less than ninety-five per cent. of actual carbolic acid), followed by a thorough sprinkling with limewash; or

(c) a disinfectant equal in disinfective efficiency to the above-mentioned solution of carbolic acid, followed by a thorough sprinkling with limewash.

(4) If any person fail to cleanse and disinfect any place or any utensil, manger, feeding-trough, pen, hurdle, harness, clothing, or other thing, or to remove any litter, in accordance with this Order, it shall be lawful for the Local Authority, without prejudice to the recovery of any penalty for the infringement of this Order, to cause such place or such utensil, manger, feeding-trough, pen, hurdle, harness, clothing, or other thing to be cleansed and disinfected, or to remove such litter, and to recover summarily from such person the expenses thereby incurred.

(5) Where the power conferred by the preceding provision of this Article is exercised by the Local Authority, the occupier of the place, and the owner of thing, to be cleansed and disinfected shall give all reasonable facilities for that purpose.

Prohibition to expose or move Animals affected with Parasitic Mange.

7.—(1) It shall not be lawful for any person—

(i) to expose a horse, ass, or mule affected with parasitic mange in a market, fair, sale yard, or other public or private place where such animals are commonly exposed for sale;

(ii) to place a horse, ass, or mule affected with parasitic mange in a lair or other place adjacent to or connected with a market, fair, or sale yard, or where such animals are commonly placed before exposure for sale;

(iii) to send or carry, or cause to be sent or carried, a horse, ass, or mule affected with parasitic mange on a railway, canal, river, or inland navigation, or in a coasting vessel;

(iv) to carry, lead, or drive, or cause to be carried, led or driven, a horse, ass, or mule affected with parasitic mange on a highway or thoroughfare, except with the written authority of an Inspector of the Local Authority;

(v) to place or keep a horse, ass, or mule affected with parasitic mange on common or uninclosed land, or in a field or place insufficiently fenced, or in a field adjoining a highway unless that field is so fenced or situate that any horse, ass, or mule therein cannot in any manner come in contact with any horse, ass, or mule passing along that highway or grazing on the sides thereof;

(vi) to graze a horse, ass, or mule affected with parasitic mange on pasture being on the sides of a highway; or

(vii) being the owner or person in charge of a horse, ass, or mule affected with parasitic mange, to allow it to stray on a highway or thoroughfare or on the sides thereof, or on common or uninclosed land, or in a field or place insufficiently fenced.

(2) Where a horse, ass, or mule is exposed or otherwise dealt with in contravention of this Article, an Inspector of the Local Authority or other officer appointed by them in that behalf may seize it and remove it, or cause it to be removed, to some convenient and isolated place to be there isolated and treated by the Local Authority in accordance with the provisions of this Order: or, on the application of the owner or person in charge of the animal, the Inspector or officer may authorise its removal with a view to its detention and treatment, and the removal of the animal by or under the authority of the Inspector or officer shall not constitute a contravention of this Article.

(3) The Local Authority may recover the expenses of the execution by them or by their Inspector or other officer of the provisions of this Article from the owner of the horse, ass, or mule seized.

Weekly Returns as to Disease.

8. When, as the result of the veterinary inquiry prescribed by Article 4 of this Order, parasitic mange is found to exist, the Local Authority of the District shall cause a return thereof to be made forthwith to the Board, on a form provided by the Board, with all particulars therein required, and shall continue so to cause a return thereof to be made on the Saturday of every week until all the diseased animals have been accounted for as killed, died or recovered.

Extension of certain Sections of Diseases of Animals Act, 1894.

9. Horses, asses, and mules shall be animals, and parasitic mange of horses, asses, and mules (in this Order called parasitic mange) shall be a disease for the purposes of this Order and of the following sections of the Act of 1894 (namely):

Section forty-three (*Police*):

Section forty-four (General Administrative Provisions);

and also for the purposes of all other sections of the said Act containing provisions relative to or consequent on the provisions of those sections and this Order, including such sections as relate to offences and legal proceedings.

Exemption of Army Veterinary Service and Veterinary Colleges.

10. Nothing in this Order applies to horses, asses, or mules which are the property of the Crown, or are in stables of military barracks or camps and under the care and supervision of the Army Veterinary Service, or to horses, asses, or mules in stables of any Veterinary College affiliated to the Royal College of Veterinary Surgeons.

Offences.

11.—(1) If a horse, ass, or mule is moved in contravention of the restrictions imposed by any Notice under this Order, the owner of the animal and the person for the time being in charge thereof, and the person causing, directing, or permitting the movement, and the consignee or other person receiving or keeping it knowing it to have been moved in contravention as aforesaid, and the occupier of the place from which the animal is moved, shall, each according to and in respect of his own acts and defaults, be deemed guilty of an offence against the Act of 1894.

(2) If any person, without lawful authority or excuse, proof whereof shall lie on him—

(i) does anything in contravention of this Order; or

(ii) where required by this Order to keep an animal separate as far as practicable, or to give notice of disease with all practicable speed, fails to do so; or

(iii) fails to do anything which by this Order he is required to do;

he shall, according to and in respect of his own acts and defaults, be deemed guilty of an offence against the Act of 1894.

Interpretation.

12. In this Order—

“The Board” means the Board of Agriculture and Fisheries;

“Inspector” includes Veterinary Inspector;

“The Act of 1894” means the Diseases of Animals Act, 1894.

Other terms have the same meaning as in the Act of 1894.

Revocation.

13.—(1) Any Order of the Board relating to parasitic mange of horses, asses, or mules, in force at the date of commencement of this Order, shall thereupon be revoked, and any Regulation made by a Local Authority under any such revoked Order shall thereupon cease to operate.

(2) Nothing in this Article shall affect the operation of a Notice served under any Order hereby revoked, or the power to withdraw such Notice.

Extent.

14. This Order extends to England and Wales and Scotland.

Commencement.

15. This Order shall come into operation on the first day of January, nineteen hundred and twelve.

Short Title.

16. This Order may be cited as the PARASITIC MANGE ORDER OF 1911.

In witness whereof the Board of Agriculture and Fisheries have hereunto set their Official Seal this L.S. twenty-second day of November, nineteen hundred and eleven.

T. H. ELLIOTT, Secretary.

* As Diseased or Exposed to Infection

A Tuberculous Cow in the Hull Market.

A dairy farmer, named William Fussey, residing at East Huntrow, Bridlington, was summoned at the Hull Police Court on Friday, November 24th, for having exposed for sale in the Hull Cattle Market a cow which was unfit for the food of man. Mr. G. C. Knee, Deputy Town Clerk, prosecuted for the Hull Corporation, and Mr. Harry Wray defended. The defendant pleaded guilty.

Mr. James McPhail, Chief Food Inspector for the port and city of Hull, stated that on Monday, the 23rd October, he found the cow in that portion of the Hull cattle market which was reserved for fat stock intended for the food of man. It had an udder which was as hard as a board. The animal, which had a bad cough, was rotten with tubercle.

The Stipendiary (Mr. J. G. Hay Halkett): As a cattle dealer and a farmer, ought he not to have known there was something wrong with the cow?

Mr. McPhail replied that the defendant ought to have known from the state of the udder and from the cough. He did not think defendant knew the cow was suffering from tuberculosis. Defendant ought to have sent it direct to the slaughterhouse to be slaughtered under proper supervision, instead of taking the risk of exposing it in the market.

Mr. Knee: If sent to the slaughterhouse, who takes the risk?—The owner.

And if to the market, who takes the risk?—The butcher loses the whole thing—the entire loss falls upon him.

Continuing, Mr. McPhail said he had during the last eight years and a half taken 1,600 carcasses affected with

tuberculosis, which had been sold for from £2 to £25 and £26, and he only knew of three cases in which the butcher got his money back in full. The purchasing butcher thought he did splendidly if he got £5 back for a beast he had paid £25 for. On the morning following the seizure in this case, the beast was condemned by the Stipendiary, and ordered to be destroyed. Upon the animal being slaughtered witness found every organ except the brain affected with tuberculosis. The udder was practically solid with tubercle.

The Stipendiary: It must be a nice thing for the people of Bridlington to know that they may have been using milk from this cow.

Witness: The cow must have been giving infected milk for six months previous to the seizure. The glands were simply huge masses of tubercle.

Cross-examined by Mr. Wray, witness said the cow was fat, and looked well. Its condition was so good that a butcher might have bought, and taken the risk.

Mr. Wray: Mr. Fussey could have sent the cow to a slaughter-house in Bridlington, where no one but he and the butcher would have seen it. I suppose there is no meat inspector.

The Stipendiary: Is there only one meat inspector for the whole of the East Riding?

Mr. Wray: I am told there is no meat inspector for the Borough of Bridlington.

The Stipendiary: If that is true, it is a scandal. A man in the East Riding with sufficient time to devote to the town would be all right; but only one meat inspector for the whole area would be absolutely dangerous.

The defendant gave evidence stating that he had lived on the farm for 21 years. He had a fall in March last,

and since that time he had not milked the cows. That duty had been done by his son, who was about 23 years of age. The cow in question weighed 44 stones, and would have sold for £11 to £13. He had no knowledge whatever of tuberculosis.

The Stipendiary: The sooner you acquire some elementary knowledge the better. It is a serious thing when milk is supplied from affected cows to children.

Defendant said he had no idea there was anything wrong with the cow, and he had kept cows for thirty years.

The Stipendiary decided to convict the defendant of sending to the market an animal which was found to be affected with general tuberculosis. There was no reason to believe that he knew the beast was suffering from that disease. But his son ought to have known from the state of the udder that there was something wrong, and something which he ought to have reported to the defendant. It was terrible to think what might have been the consequences if the cow had been sold for human food and consumed in that city or elsewhere.

There would be a fine of £5, including costs.

Mr. J. W. Hardy, Chief Assistant Food Inspector, Hull, was called into court, and, in reply to the Stipendiary, said there was no regular meat inspector in Bridlington.

Mr. Knee said that was practically the case in many other places.

The Stipendiary: It is a very serious state of affairs. It may be common, but it is not desirable.—*The Yorkshire Post*.

Next Year's Thoroughbred Stallion Show.

The Board of Agriculture has just issued its premium regulations for 1912.

In lieu of a travelling fee of 10s. 6d. for each mare served, a sum of 50 gs. will be paid to the stallion owner after the close of the season on production of a certificate that the stallion has regularly travelled the district for which it was awarded a premium.

Every stallion must be registered under the Board's registration scheme before it can be accepted for entry. The registration year is November 1st to October 31st, and re-registration will only be undertaken between November 1st and March 1st.

A stallion will not be registered or retained on the register unless it is certified to be sound and suitable for breeding purposes, and is free from the following diseases and defects:—Cataract, roaring, whistling, ringbone, sidebone, bone spavin, navicular disease, shivering, stringhalt, defective genital organs.

No veterinary examination will be made at the show.

Tuberculous Pork.

A Thames Police Court on Saturday last, before Mr. Dickinson, Frederick Thompson, grocer, of Bradford Street, Bocking, Essex, was summoned as the owner of a diseased pig which was sent to the London market.

Mr. Young, who prosecuted on behalf of the Stepney Borough Council, said on October 27 Mr. H. Abson, food inspector, saw a hamper outside a shop in Whitechapel, and attached to it was a label bearing the defendant's name and address. The hamper contained seven pigs' carcasses. Two carcasses had certain glands removed. The third carcass, the subject of that summons, was extensively affected with tuberculosis.

Dr. D. L. Thomas, Medical Officer of Health, said the throat glands of the pig were affected with tuberculosis, and that rendered the whole carcass unfit for human food. It was true there was some modification of that rule at Smithfield, and in consequence he com-

municated with the Local Government Board. He received a reply that since the last Royal Commission there had been no modification of the regulations.

On behalf of the defendant, Mr. C. E. Jones, barrister, said his client bought the pigs from a well-known auctioneer, and a good price was given for them. The defendant did not do his own killing.

The defendant said he gave 46s. 6d. for the pig, and that was a good market price.

The slaughterer of the pig, J. Nash, of Cressing Road, Braintree, was then summoned for knowingly allowing the carcass to be sent to London.

Mr. Jones said Nash had no idea that there was anything wrong with the pig.

Mr. Dickinson remarked that the amount of carelessness exhibited in the case was very great indeed.

Mr. Young said Nash had previously been fined £20 and £5 5s. costs for a similar offence.

Mr. Dickinson fined Thompson £15 15s. and £5 5s. costs, and Nash £42 and £10 10s. costs.

Neglect of a Horse at a Railway Station.

At Howder on Saturday, Harry Boynton, railway porter, of Staddlethorpe, was charged with cruelty to a horse. Inspector Wilson, of the R.S.P.C.A., said that on October 14th last a horse was sent from Goole to a horse slaughterer named Webster, of Gilderdyke. The animal reached Staddlethorpe Station, on the North-Eastern Railway, at 4 p.m., and defendant, who was foreman porter on duty, had the horse box detached and shunted into a siding, and left it. It was defendant's duty, said Inspector Wilson, to see that the horse box was unloaded and white-washed, but he did not do this, and the horse remained in the box, without food or water, from Saturday afternoon till Tuesday morning. The stationmaster then had the horse watered, and sent to Webster's premises. The animal died before it could be shot.

Thomas Leeson, stationmaster at Staddlethorpe, said he was not aware till the Tuesday that there was an animal in the horse box. It was Boynton's duty to see that the box was unloaded and cleaned out. In answer to Mr. Laverack, of Hull, who defended, witness said it was perhaps his duty to see whether there was a horse in the box or not. It was his duty to advise the consignee, but this was not done.

Mr. Laverack submitted that there was no case against defendant. The Bench must find that defendant knew the animal was not being fed and watered.

The Chairman of the Bench (Mr. Schofield) said there had been extraordinary laxity all round. They ordered defendant to pay the costs of the case.—*The Yorkshire Post*.

Dumfries Filly Case.

In Dumfries Sheriff Court on Friday, November 17th, Sheriff Campion heard parties' agents on the proof in the action. [The proof appeared in our issue of November 18th.]

Mr. John Irving argued the case for defender, and Mr. John M. Haining, appeared for the pursuer.

Mr. Irving said they had some remarkable evidence regarding the price of the filly. The pursuer told them that Mr. Houston, V.S., Paisley, offered £100 for her on the 3rd June; and it was rather remarkable that on the 20th June, after she had been mated with one of the best horses in the country, that he then accepted £100, notwithstanding that he would have had to pay a considerable fee and that her value would be a good deal increased. It was suggested that Mr. Berwick wanted out of the bargain, but the correspondence, which had a strong bearing on the case, showed that there was not

the slightest ground for such an impression. He pointed out that Professor John R. M'Call, Glasgow, in his certificate mentioned that there was a splint on the near fore leg. That, therefore, was merely a qualified certificate, and did not bear out the warranty given by the pursuer of "soundness and correctness in every respect." It was also noteworthy that Prof. M'Call never saw the large articulation and prominent processes referred to by his father, Principal M'Call. It was, he thought, a suspicious circumstance that Mr. Watson, pursuer's Glasgow agent, on 4th July wrote that he had the certificate of two eminent veterinary surgeons to disprove that the filly had ringbone, and yet one of these veterinary surgeons, Mr. Andrew Robb, in cross-examination stated that he did not send his certificate till the 5th July. His friend in his cross-examination of the veterinary experts, tried to make much of Mr. M'Intosh being called in, and made rather grave insinuations. But he asked his lordship to observe that Mr. M'Intosh had not been Mr. Berwick's veterinary surgeon for many years. The suggestion of his friend seemed to be this. Mr. Berwick and Mr. M'Intosh were friendly, consequently Mr. Berwick went to Mr. M'Intosh and tried to get him out of a rue-bargain. It was unthinkable that men like Principal Dewar, Edinburgh, and Mr. M'Intosh would go into the witness-box and deliberately tell what they did not find. The whole of his expert witnesses had spoken to the filly being lame. If Mr. Berwick had wished to get out of the bargain he would have asked Mr. M'Intosh and his other witnesses to examine the filly generally. Instead of that they were asked to report only as to the animal's pasterns. On five occasions Mr. M'Intosh examined the filly, and found her lame four times. So that there was not the shadow of a doubt that the filly was lame, or that that lameness was due to ringbone. He quoted from Mr. Ross Stewart on "The Law of Horses" to show that the bare affirmation that a horse was sound was not *per se* a warranty. They had another suspicious circumstance. That was when the experts went to see the filly at West Linton she was found not in a park or field as they would have expected at that season of the year, but in a loose-box and with a "cradle" on her neck. That showed she was being treated. The pursuer said that was for hair; but if that were so the treatment would have been applied all round to the four pasterns. Instead of that the treatment was only applied to the faulty fore pasterns. An exhibitor would naturally want hair on all four feet. It was also extremely suspicious for this reason, that at that season of the year the hair was coming off. Mr. Irving said they had thirteen witnesses for the pursuer, and they were rather a curious combination. He showed that nearly all of them were related one to the other. It was also noteworthy that they gave evidence which was really outwith that case—they did not tell whether the filly had ringbone or not.

The Sheriff: The evidence of Mr. John C. Johnstone, Peebles, rather impressed me. He examined the filly for the insurance company.

Mr. Irving: That was for foaling risks—whether she was in a state to carry a foal and in such a state as the insurance company would care to take the risk. That is entirely different to an examination for the purpose of finding if any particular parts are at fault.

The Sheriff: The insurance company were anxious for a veterinary certificate before insuring her to see if she was sound.

Mr. Irving: Yes, my lord; but that applies to the filly coming to the foaling.

The Sheriff: That does not come out in the evidence. He says that the pastern joints were in keeping with the rest of the filly.

Mr. Irving: He would not have his mind on the pastern joints to the extent that the witnesses for the defender had. He pointed out as against the case for the

pursuer that none of the seven experts for the defender said anything about large articulations or prominent processes. Their evidence all went to show that there was nothing unusual about the filly's pastern at all. On the pursuer's side they were simply reduced to the testimony of Principal M'Call, whose evidence that there were prominent processes was against all the opinions of the experts for the defender. So that they had one man who said there was no disease, and eight who found distinct symptoms and traces of disease—in fact disease itself. They had absolutely no veterinary authority in any of the text-books, so far as he was aware, to show that prominent processes could be mistaken for ringbone. As against the theory of the witnesses for the pursuer that it was so unusual to have a horse so young with ringbone, he referred to the case pending this week in the Kirkcudbright court, where they had a young animal with ringbone, and moreover they had as one of the witnesses who testified to the ringbone, Principal M'Call. He submitted that his experts were not deceived, and he had proved beyond doubt that the animal was unsound from ringbone.

Mr. Haining pointed out that this was the first time the pursuer had been in court. He referred to the case of *Scott v. Steel* in 1837, where it was found that it was not necessary to use the words "I warrant" to guarantee a horse.

The Sheriff: I don't think there is much trouble about the warranty here.

Mr. Haining, in dealing with the purchase of the filly, called attention to the fact that Mr. Berwick had stated in his evidence that at Newton-Mearns he put his hand on the filly's shoulder, but never put his hand on the hoof heads. "Now, frankly," said the agent, "I don't think anyone conversant with horse dealing matters would be prepared to believe a statement such as that. Mr. Berwick is not purchasing a filly like that every week, or I suppose every year." It was admitted that this was a beautiful filly, and there was a suspicion that Mr. Berwick rashly and incautiously gave £50 more than he intended to do. The bargain was completed in a hurry at Langside station, and the whole situation was summed up in this—that Mr. Berwick had repented of his bargain. He argued that the history of the filly discredited the idea that she suffered from ringbone through heredity.

The Sheriff: No doubt it can arise through an accident.

Mr. Haining pointed out that they had great variations in the evidence for the defence as to the position of the ringbone, and the stages at which it was, and also with regard to lameness. Three judges at Cathcart show saw no ringbone about the filly, and apart from his other witnesses he had the evidence that there was no ringbone from one of the best known experts in the country, Principal M'Call. He referred to the point to which Mr. Irving had called attention, with regard to the date of Mr. Robb's certificate, and said that Mr. Watson was in the neighbourhood on that day, 4th July, when the examination was made.

The Sheriff: I am not troubling much about that. He knew he was going to get it.

Mr. Haining held that in the whole circumstances defender had failed to discharge the onus which was placed upon him, to prove that there was ringbone about the filly.

The Sheriff took the case to *avizandum*.

INTERLOCUTOR.

The Sheriff-Substitute, having considered the proofs and whole process after a debate thereon, finds (1) that the defender, wishing to purchase a filly for breeding purposes, offered on 20th June, 1911, to buy from the pursuer a filly named Sweet Bloom for the sum of £100, on condition that the pursuer gave a guarantee of sound-

ness in every respect; (2) that after repeated letters of request, the defender ultimately received such guarantee on 30th June, 1911, and in consequence wrote the pursuer to send on the filly; (3) that the filly Sweet Bloom was duly consigned and delivered to defender on 3rd July, 1911; and (4) that on same day, 3rd July, the filly on being examined was found to be suffering from ringbone on both fore feet, and to be unsound. Finds that the defender having purchased the filly from the pursuer on an express guarantee of soundness, the defender was entitled to reject her; therefore sustains the pleas-in-law stated for the defender; assolizises him from the conclusions of the action, and decerns. Finds the defender entitled to expenses; allows an account thereof to be given in, and remits the same when lodged to the auditor of court to tax and report.

GEO. CAMPION.

NOTE.—This action is brought to recover payment of the price of a filly, Sweet Bloom, said to have been sold by the pursuer to the defender on or about 20th June, 1911. The defence is that the filly was warranted sound, but upon veterinary examination was found to be suffering from ringbone on both fore feet, and so to be unsound and disconform to warranty.

In answer to a letter from pursuer of 19th June that he had a good mare and two two-year old fillies, the defender, who wished to purchase a filly for breeding purposes, went to the pursuer's farm on 20th June. He was there shown a two-year old filly named Sweet Bloom, the price of which was settled at the railway station before the defender left to be £100.

On 21st June the defender wrote to the pursuer to confirm his offer of £100 for the filly, "on the understanding that you guarantee her sound in every respect. It is to be noted that in the pursuer's letter of 19th June to defender there is an unmistakable guarantee of the mare "as thoroughly sound and correct in every way," but the guarantee letter is so framed as not to cover the fillies. In reply to further letters of 23rd, 26th, and 28th June, that unless the pursuer confirms the guarantee of soundness the transaction is off, the defender is put off with the answer that Sweet Bloom is sound and her price is £100. It is only when the defender writes on 28th June that "you either cannot or will not do so," and the pursuer replies on 29th June: "I have guaranteed her sound and correct in every respect," that the defender is satisfied and orders the filly to be sent on.

It is immaterial for this action whether the verbal assurance made at the farm, and repeated in pursuer's letters of 27th and 28th June, that "Sweet Bloom is sound," would be held as a guarantee or as a mere expression of opinion. The defender declined to accept as a sufficient guarantee. It is clear he was pressing for such a guarantee, for instance, as the pursuer had volunteered of the mare in his first letter of 19th June, and not till he gets such a guarantee is he prepared to conclude the bargain. The filly is accordingly sent on to Albany Bank on 3rd July, when the defender saw her within a few minutes of her arrival, and upon examination says he found enlargement round each fore coronet, the defect being quite evident. He at once called in Mr. McIntosh, the consulting veterinary surgeon for the county of Dumfries, who after making a special examination of the two fore pasterns gives the certificate No. 102 of process, that the filly is unsound from ringbone in both fore feet. Ringbone of that size, Mr. McIntosh tells us, could not have been there less than two months.

Ringbone is held to constitute unsoundness, so if this certificate is correct, the defender having purchased only after a guarantee of soundness, is entitled to reject her. This the defender did by letter of 3rd July, returning her to the pursuer on the following day, and on 4th July received from Mr. Watson, writer, Glasgow, infor-

mation that the filly had been placed in the custody of Messrs. Shand, livery stable keepers, Langside, and, further, that he holds the "certificate of two eminently qualified veterinary surgeons, viz., Prof. McCall and Mr. Andrew Robb, F.R.C.V.S., regarding their examination of said filly," which are to be used to disprove the certificate of Mr. McIntosh.

Prof. McCall's certificate, it is to be noted, is of 1st July, 1911, before any question had been raised as to the unsoundness of the filly, and on the Saturday before the Monday she was sent off.

On 12th July the defender, in company with Principal Dewar and Mr. McIntosh, saw the filly in the livery stables at Langside, when she was in the same condition as when examined at Albany Bank. This opinion is confirmed by the certificate of Principal Dewar, No. 104 of process, to the effect, "she has ringbone on each fore pastern, a splint on the near fore leg, is lame on the off fore, and unsound."

On 15th July the defender, in company with Mr. Spruell, saw the filly at the same place, but to find her in the same state as before. And, again, the defender examined and found her in the same state when he was, by arrangement between parties, sold at Lunark on 28th August. The filly was then sold to Mr. Lorimer, Callands House, West Linton, where she was on 30th September visited by the defender in company with Mr. McCallum, V.S., and Mr. Storie, V.S. This is a surprise visit, when the filly is found in a loose-box wearing a cradle to prevent her getting at her feet, which Mr. Lorimer explains are being blistered to improve the hair, and on being trotted out is found decidedly lame.

All the witnesses adduced for the defender most definitely support defender's contention and Mr. McIntosh's original conclusion that the filly is suffering from ringbone on each fore pastern, and is lame on the off fore. The question arises then, is it possible to confuse ringbone with anything else, or anything else with ringbone? Mr. McIntosh is clear, and no one who knows his business would do so. Principal Dewar says ringbone or the symptoms could not be confused with any other disease by a man who knows his business at all; Mr. Spruell, that it could not be mistaken for any other complaint that he knows of; Mr. Baird, that the symptoms could not be mistaken for those of any other disease; Mr. Macfarlane that the same symptoms are not found in a sound animal; Mr. McCallum, that "the symptoms of ringbone cannot be mistaken for any other disease, or for any natural enlargement of the bone"; and Mr. Storie that "these symptoms could not have been mistaken for any other disease; they could not be confused with natural formations or large articulations."

Ringbone is admittedly a somewhat rare complaint in an animal of the age of this filly, and we have a volume of evidence in support of the pursuer's contention that the filly exhibits no trace of ringbone. A dozen witnesses who have examined her testify that in their opinion the filly is sound. I have most carefully studied their evidence, and can only say I do not profess to account for evidence so absolutely contradictory of that led for the defender. One can only surmise that there must be ways and ways of looking for symptoms of ringbone; some ways being better than others to disclose the feature. But whatever the explanation, having given the whole case the most careful consideration, I prefer the direct positive evidence adduced for the defender to the negative, and to a certain extent speculative, professional evidence on the other side.

Then, too, the surrounding circumstances of the transaction, from the commencement, appear to me to support the defender's contention. The letter of 19th, so framed as to exclude the fillies from the unqualified guarantee given to the mare; the pursuer's persistent

reluctance to furnish the defender with the guarantee he was obviously asking for; the apparently uncalled-for veterinary examination of the filly on 1st July, before there was any question of unsoundness raised. The pursuer would account for this by saying he thought the defender wanted to be out of the "deal." I see no grounds for such a suggestion, and we have before us all the pursuer had, that is the correspondence between the parties after 20th June. The defender was evidently going to trouble and expense to get the filly he wanted, but was determined to have an undeniable guarantee of soundness as he was paying what he calls a "sound" price. All this inclines one to question whether the pursuer, who describes himself as a "competent judge of horseflesh," with 41 years' experience, did not entertain some suspicion in his own mind whether he was in a position to give the filly the same unqualified guarantee he was ready to give to the mare. Further, when the defender pays his surprise visit to Callands House in company with Mr. McCallum and Mr. Storie, whether to stimulate growth of hair or not, the filly is found being doctored for something, and when trotted out to be decidedly lame. On the whole case I am of opinion that the defender has proved that the filly was suffering from ringbone when sold to him, and that he was therefore entitled to reject her as unsound. (Intd.) G. C.

Lieut. L. L. Dixon to be Capt., with precedence next below Capt. T. Bone. Dated Sept. 5.

Lient. H. S. Woods resigns his commission. Dated Nov. 25.

OBITUARY.

ISAAC JAMES, M.R.C.V.S., Corsham, Wilts.

Graduated, Lond : April, 1866.

The death on Tuesday morning of Mr. Isaac James, of Pickwick Road, threw the whole village into mourning, for the late Mr. James had during his stay in Corsham made himself generally respected. Besides being Coroner for the last 12 months, he held office of Inspector of contagious diseases. On Tuesday evening it was the painful duty of the new Coroner for Corsham (Mr. W. H. Beszant), elected but two hours before, to conduct an inquiry into the circumstances of the death.

Before the inquiry was opened Mr. Barrett, on behalf of the Steward of the Manor, who much regretted his inability to be present, expressed on behalf of the Court of Leet and Baron how much they regretted the sad loss which the parish had sustained by the death of the late Coroner and the deepest sympathy of the Court with the family in their bereavement.

The Coroner also made a feeling allusion to the loss which the parish had sustained, and expressed sympathy with the bereaved family.

Miss Rose James, a daughter of the deceased, gave evidence of identification, and said after breakfast on the previous morning her father went into the yard. Later in the morning she went into a loft over the stables, and there she found him sitting down in the straw. She thought he was dead, and immediately called her sister, Dr. Wood being sent for. Her father had not been well since he was hurt by a cow a fortnight ago, but previous to this he had been in good health. Her father had since the accident been having sleepless nights, and no doubt the sleeplessness from which he suffered made him very nervous. When she found her father in this condition she gave him some brandy to revive him, but it was of no use.

Dr. A. G. Wood, of Corsham, said that at 9.45 on the previous morning he was sent for to see Mr. James. He found him in the loft, and life was extinct. The body was still warm, and the breath smelt of spirits. He concluded from the coldness of the morning that death must have ensued shortly before. Mr. James had been under his care for about a fortnight. He had a very severe blow in the mouth from a cow. The blow cut his mouth, knocked one tooth out, and broke another. About 18 or 20 years ago Mr. James had a very severe attack of neurasthenia, and the result of this blow was to upset his nervous system again, bringing on the usual symptoms—irritability of temper, extreme nervousness, and want of sleep extending over a long period. Owing to these symptoms he searched Mr. James' pockets but found nothing there. He then had the body removed into the house and made a search in the straw.

Just where his hand would have been, said Dr. Wood, he found a bottle labelled "Prussic acid." The bottle was one which contained an ounce, and a fatal dose would be two teaspoonfuls. Death would ensue in from two to ten minutes. The bottle smelt strongly of prussic acid, and he believed the cause of death was owing to the effects of prussic acid. Suffering as he was, Mr. James was certainly not responsible for his actions. Worn out by sleepless nights, he had lost control of himself, and was therefore temporarily insane. The bottle had evidently come from a wholesale house, and the poison was evidently used by the deceased in the pursuit of his occupation as a veterinary surgeon. The bottle would hold about seven or eight teaspoonfuls of prussic acid, and there was only half a teaspoonful left in the bottle.

The jury returned a verdict of "Suicide during a temporary derangement of the mind."—*Bath and Wilts Chronicle*.

The late Mr. W. T. Sabin, M.R.C.V.S.

We are indebted to Mr. C. J. Reakes for the following note:—

"It is with the deepest regret that the death of Mr. W. T. Sabin, M.R.C.V.S., Veterinary Supervisor for the Southland District of New Zealand is chronicled. Mr. Sabin contracted pneumonia, and succumbed after an illness lasting some three weeks. The deceased gentleman joined the Department of Agriculture in October, 1904, having previously been for several years engaged in private practice at Hastings, Hawke's Bay. He was a most capable and trustworthy officer, well versed in his profession, and he did a great amount of valuable and effective work in a quiet and unostentatious manner. His death is a severe loss to the Department.

Mr. Sabin studied at the London Veterinary College, graduating in 1870. On entering the Government service he was first appointed to Ashburton as Veterinary Inspector at the Canterbury Frozen Meat Company's Freezing Works, and in January, 1905, was transferred to Pareora as Veterinary Inspector at the same Company's works there, about a year later being transferred to Invercargill, where he subsequently held the position of Veterinary Supervisor for the Southland district until the date of his death.

The death occurred at Invercargill on Wednesday Oct. 11, of Mr. William Thomas Sabin, at the age of 61 years. Deceased was born at Oxford (England) and came to New Zealand in 1886, where he had followed the profession of veterinarian until his death. He first settled in Otane (Hawke's Bay), where he was in private practice for five years, when he removed to Hastings, remaining in that district for some seven years. He then joined the Stock Department, and for the past six years had been Government Veterinarian and Meat Inspector for the Southland district.

Mr. Sabin was in his usual health until three weeks ago, when he caught a chill, and on medical advice became a patient in a private hospital, a bad attack of pneumonia having supervened. His condition became serious, but a week ago there was hope that he would pull through. Complications, however, followed, and death occurred.

Deceased was one of the most valued members of the veterinary profession in New Zealand, and at the time of the outbreak of black-quarter amongst calves in the Taranaki district, to him was entrusted the responsibility of inquiring into the matter. Mr. Sabin was of a reserved disposition, so did not make many acquaintances, but his generous nature and other good qualities won for him the high esteem of those with whom he came in contact. An enthusiastic angler, deceased occupied a good deal of his leisure at this popular pastime, and having made a close and intelligent study of the habits of trout, his conversation on the subject was always interesting and instructive. Deceased leaves four sisters and two brothers, all of whom reside in Hawke's Bay. Of the latter, one is Mr. C. S. Sabin, farmer, Onga Onga, and the other Mr. A. J. Sabin, builder.—*The Southland News*.

To the Editor of *The Veterinary Record*.

Mr. Sabin died of septic pneumonia on Oct. 11th. There may be members of the profession in the old country who remember him. I only knew him a few months, and regret his sudden death; he was a man worth knowing; he took a deep interest in everything pertaining to his profession, and although not in private practice, read much, and kept himself well abreast of the times. The funeral was attended by Mr. Edwards, M.R.C.V.S., Mr. Waugh, M.R.C.V.S., and myself.—Yours truly,

JOHN MILLER, M.R.C.V.S.

[Mr. Sabin was a subscriber to *The Record* since January, 1891, and both Editor and Publishers are indebted to him for welcome words of encouragement and appreciation over a number of years].

The late Capt. B. H. Lane, A.V.C.

By the death of Capt. B. H. Lane, A.V.C., who died on Sunday, Nov. 5th, from injuries received while riding in the Calcutta Turf Club Chase at Meerut on the previous Thursday, the Army Veterinary Corps loses one of the most popular officers it has ever possessed. Probably no officer was better known or more respected throughout the whole of Northern India. He was always good company, a sincere friend, and a most honourable sportsman. Whether on the racecourse, the polo ground, or in the boxing ring, Capt. Lane could always manage to hold more than his own, and at the same time be on the very best of terms with one and all of his opponents. The deceased officer's skill in the saddle was phenomenal, and many will remember how, when riding "Leading Lady" in a steeplechase at Rawalpindi last January, his mount turned a complete somersault on landing over one of the jumps, but Lane was in the saddle before the mare was able to rise, went in pursuit of the others, and eventually won the race amidst the acclamations of the spectators and bookmakers. Though his winning meant loss to the latter, they could not refrain from applauding the pluck, determination, and skill shown by the gallant rider. To give another instance of his remarkable horsemanship, he had just a few weeks before that, in consequence of his girths slipping back, won a mile and a half hurdle race carrying his saddle and a stone of lead in weight cloths in his left hand. Nowhere in India will the loss of the deceased officer be more felt than in Rawalpindi, where he was for some time stationed, and where he was extremely popular. Particularly will his untimely death be felt by the officers of the 10th Royal Hussars. The deceased officer had only completed seven years of service, and had not yet reached the age of thirty. It is one of the ironies of fate that his tour of Indian service would have expired in January.—*Civil and Military Gazette*, Lahore.

A correspondent adds:—"Capt. Lane was picked up insensible after a heavy fall and never recovered consciousness."

CORRESPONDENCE.**GASTRIC AFFECTIONS OF RUMINANTS.**

Sir,

The first quarter of Mr. Stewart's letter, which appeared in last week's *Veterinary Record* on the above subject, is interesting and reasonable, although, no doubt, many of your readers will not be able to agree with what the author says about the effect of salts on the chewing of the cud. These are Mr. Stewart's words:

"Large quantities of salts, when given to cattle, enter the rumen and mix with its contents. The taste of the salts is disagreeable to animals, and consequently they refuse to chew the cud, and the bolus is returned to the rumen without being masticated."

I can quite believe that Mr. Stewart has seen a bolus brought up from the rumen, and returned without being masticated. But when he says it is returned to the rumen I, for one, don't agree with him. Of course if Mr. Stewart has discovered or procured something by which he can faithfully follow the course of the returning bolus, then he is justified in making such a statement, but not without. If a bolus tasting of salts is returned to the rumen as he states, then by what process of reasoning does he arrive at the conclusion that a ball of aloes passes at once into the omasum. Further, what is the use of a physic ball passing into the omasum in a case of impaction of the rumen.

If a beast chews its cud alright, it is not likely to be the subject of gastric derangement, and the practice of giving a ball of aloes in such a case does not seem to me at all good or rational treatment. In gastric affections of cattle, as a rule, the process of "chewing the cud" is suspended, and this fact alone is one of our best guides to the seat of the trouble. In my experience the action of salts on cattle is neither violent nor drastic, as Mr. Stewart states. Suppose he was called to a case of acute tympany in a cow. He says that for such cases he now uses the probang only, and finds this greatly superior to the use of either the trochar or canula. I do not dispute this, but I should much prefer the quicker method, and the one which does not require two men to assist the operator, is just as effective, and is not attended with nearly so much risk.

Lastly, tympany means "tympany of the rumen" as a rule when applied to cattle, and if Mr. Stewart gives an eight or nine dram ball after he has passed the probang, and this ball "at once passes into the omasum" what can be the theory on which such a procedure is based.—Yours faithfully,

W. E. BLACKWELL, M.R.C.V.S.

Towcester, Northants.

VETERINARY SURGEONS AND MEAT INSPECTION

Sir,

I read with pleasure Principal M'Call's spirited letter to *The Scottish Farmer* in *The Record* the other week, and I hope more often to defend the academic attainments of the veterinary profession in future when the occasion arises. We have become so accustomed of late to the veterinary profession, probably from an over developed sense of modesty, underestimating these attainments, and fawning under the smile of every medical man, who, in all sincerity and with good intentions doubtless, but with a lamentable lack of knowledge of veterinary education, dons the mantle of the prophet, that some of us are getting somewhat sceptical of the usual prophetic advice, which can generally be summed up in a few words, viz., take a post-graduate course and you will obtain a great privilege, and to have serious doubts as to whether that privilege, which means the inspection of meat at £150 a year, can be called by that appellation.

Far be it from me to deprecate post-graduate instruction, but with Principal M'Call, I contend that a V.S. if he has graduated after 1895, from his training in pathology, bacteriology, and meat inspection, to say nothing of other subjects, is the best qualified person to give the best opinion on the morbid conditions of animals alive and dead. Recent graduates will readily admit that throughout their curriculum the above subjects were perhaps more thoroughly taught than any of the others, and will fail to recognise where the inducement lies for further training in subjects they have had a thorough grounding in.

If a layman, by taking a short course in meat inspection, can render himself capable of performing the duties pertaining to that occupation—and for ordinary inspection I fail to see why he cannot—surely an intelligent V.S., from his more extended studies, is much more proficient. It ought to be as plain as one of Euclid's axioms. Why then humiliate him by compelling him to take a meat inspector's certificate.

If veterinary surgeons aspired to positions such as agricultural analysts, biologists, entomologists, expert advisors in sanitary matters to Councils, and positions of eminence in agricultural science or pure science, one could quite understand their wishing to take the very necessary step of acquiring further and deeper knowledge in the subjects they wish to specialise by attending a course of instruction under leading experts, but when one sees them ready to bawl from the housetops that without a layman's certificate they are unable to perform the duties which are their birthright, one marvels but can quite understand the attitude of the public. We are taken over at our own valuation.

When many of the above positions at home and abroad, positions that lie eminently in the province of veterinary science, are filled by men who have taken a "two years'

course in agriculture, or a diploma in dairying, it is time for the profession to shake off this meat inspection mania, and expend its energies in striving to obtain something better than petty privileges such as the sticking of crests on the backs of envelopes.

The Royal College of Veterinary Surgeons will have to read the signs of the times and look a little way into futurity. The writing on the wall is getting plain enough. It does not require a big stretch of the imagination to see that, owing to the rapid development of our Colonies the scarcity of labour, and the development of motor power, the number of horses (our chief patients) in these islands in a few years will be able to be divided by two. England is rapidly becoming a grazing country, and her towns horseless.

Future education should be shaped accordingly to enable graduates to secure positions not only in the higher branches of preventative medicine and public health, but also in positions pertaining to agricultural and pure science. Fuller courses of instruction should be given in our schools on subjects such as foods and feeding stuffs, their analysis and adulteration, economic principles of feeding, breeds and breeding, ventilation, building construction and the principles of sanitation, insects and parasites injurious to plant and animal life on the farm, milk and dairy bacteriology, diseases of animals other than the horse should receive greater attention. Stable management, which at present costs the student about a month's mental anxiety before examination and commands the respect of two examiners, should be diffused throughout the curriculum, and the energies of these two adjudicators expended with a greater degree of educational profit on some of the above mentioned subjects. There lies a weak spot for the Council to start upon without incurring any additional expense.

If it is decreed that such innovations cannot be carried out, then let us have post-graduate courses of wide calibre in our Colleges, with arrangements with Agricultural Departments of Universities for the teaching of subjects bearing on the more agricultural problems; but we must bear in mind that many of our graduates go abroad and would be unable to avail themselves of such an arrangement, therefore fuller ante-graduate instruction is preferable, to give these men a sufficient ground work to enable them to keep up to date by the perusal of current literature, and to successfully hold their own against Colonial graduates.—Yours, etc.,

A GRADUATE SINCE 1895.

VETERINARY EVIDENCE.

Sir,

I read with a great deal of interest, in your issue of the 18th inst. the report of the "Horse Action at Dumfries." There is, to the ordinary practitioner, small cause of satisfaction in the reflection that some of our "leading lights" on one side or the other must be making mistakes as grievous as he himself can make. There are seven or eight veterinary surgeons, and some are eminent men, on either side, and I think all are very nearly sure they are quite right and those on the opposing side quite wrong. The first three witnesses for the defence are each reported as saying that any professional man who knows his "work," "profession," or "business" must have diagnosed as they did. The fourth witness says there is ringbone of the off fore coronet, half as large as a bantam's egg, and the fifth corroborates, and adds that the symptoms could not be mistaken for naturally large articulation of the joint. And upon the pursuer's side we get equally positive evidence. The first three witnesses are sure the animal is absolutely sound. Prof. McCall is sure there is no ringbone, and Principal M'Call that the filly has "very prominent processes" but no sign of disease. In view of such marked differences of professional opinion I think it is not much to be wondered at that so many stockowners are apt to think they know quite as much regarding domestic animals as the veterinary surgeon. It almost makes one believe that in some such cases a little clever "shuffling" is carried out, so that the witnesses on one side are shown a different (but of course similar) animal to that shown to the others.—I am,

"PUZZLED."

"Marvellous Results in Pneumonia."

NUCLEIN (P., D. & Co.), when administered to animals, produces an enormous increase of leucocytes in the blood, and thereby greatly enhances disease-resistance. Hahn states (*Berlin. klin. Wochenschr.*, Nov. 28, 1896) that with **Nuclein** (P., D. & Co.) "it is easy to double the original number of leucocytes in a short time. This remarkable property renders the drug of great value in the treatment of

Pneumonia Pleurisy Strangles Purpura Hæmorrhagica Umbilical Infection
Influenza Lymphangitis Laryngitis Wound Infections Epizootic Cellulitis
 and other Pathological Changes due to Bacteria.

VETERINARIANS' REPORTS.

Pneumonia.

E. R. VOORHEES states in the *American Veterinary Review* that **Nuclein** has produced results which at times "seemed marvellous," and instances an apparently hopeless case of double pneumonia which recovered rapidly after the injection of **Nuclein**. Also see article by E. M. PERRY in *The Veterinary News* of Nov. 19, 1910, and by D. HANNAY in *The Veterinary Record*, Mar. 11, p. 589.

Fistula, Poll Evil, Septicæmia.

A report appears in *The Veterinary News* of Feb. 4, 1911 (p. 67), of the prompt improvement brought about by **Nuclein** in cases of fistula and poll evil which had failed to respond to other methods of treatment. A case of profound toxæmia in a dog which was greatly benefited by **Nuclein** is reported in *The Veterinary News* of Feb. 16, 1907 (p. 109).

NUCLEIN SOLUTION (P., D. & Co.) is supplied in bottles of 1 and 4 fluid ounces, also in hermetically-sealed glass bulbs containing one dose diluted with physiological sodium chloride solution suitable for intramuscular injection.

NUCLEIN SOLUTION No. 2 (P., D. & Co.), for oral use, is supplied in bottles of 4, 8 and 16 fluid ounces.

Influenza.

C. D. GRUBER writes in *Veterinary Notes*, Mar., 1908: "I am not afraid to undertake the treatment of the most severe case of influenza and its complications, also all respiratory diseases which are due to infection, provided I have a supply of **Nuclein Solution**."

Canine Distemper.

J. PEDDIE, F.R.C.V.S., reports as follows in *The Veterinary Journal* for December 1910: "I have, in all, treated 32 cases of distemper with the aid of **Nuclein**, and have had only four deaths, a percentage of recoveries I could not have hoped for with the treatment previously adopted.... The majority of cases have not been by any means mild ones, and I have not got them very early.... I am firmly of opinion that **nuclein** is a most valuable agent in the treatment of distemper."

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" flat mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

12 RED LION SQUARE LONDON, W.C.

Royal Veterinary College, London.

(Founded 1791.)

Principal and Dean: Professor **SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.**

Membership Diploma of the Royal College of Veterinary Surgeons:

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities, etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.), which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts, and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 7th, and terminate on Friday, November 29th, 1912.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

Royal Veterinary College, Camden Town, N.W.

PRACTICES FOR DISPOSAL

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

HOME COUNTY. Receipts £350 to £400 per ann. Rent £35. Premium required £200.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SCOTLAND. Returning over £300 per annum. Expenses very low. Premium £120, or nearest offer.

YORKSHIRE. Receipts 1910 £332. Rent £19. Premium £300.

"MAGNUM" PESSARIES.

(HEWLETT'S)

"Magnum" Pessaries are prepared with a medicated non-oily base which is both effective as a Uterine Antiseptic and of special benefit in Parturition both in Cows and Mares.

A "Magnum" Pessary should be inserted directly after parturition in order to maintain the Uterus in a healthy state. It can be inserted with the greatest ease and will keep the parts in a thoroughly antiseptic condition for a lengthy period.

Alkaline "Magnum" Pessaries have recently been recommended to neutralise excessive acidity of Vaginal secretion.

"Magnum" Pessaries are supplied according to various formulæ as below, and Veterinary Surgeons' own formulæ can be made up as required.

"Magnum" Pessaries,		Doz.	12 doz.	Doz.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1222.

DECEMBER 9, 1911.

VOL. XXIV.

THE COAL MINES BILL.

The deputation from the R.C.V.S., whose conference with the Chief Inspector of Mines upon the Coal Mines Bill we publish to-day, was a small one, and had necessarily been very hurriedly convened. But it was composed of men peculiarly well fitted for the task they undertook, and one good result seems directly attributable to their influence. Not "a competent person," but a duly qualified veterinary surgeon is alone to be entrusted with the testing of horses for glanders before their descent into the mines. That amendment, which may mean much more to the public than it does to us, was accepted by the Government when the Bill was read a third time on Tuesday last; and it was the alteration most strongly urged by the deputation of November 30.

Great credit belongs to the R.C.V.S. for prompt action at short notice; and no less is due to some individual members of the profession. Of the five veterinary surgeons upon the deputation, four came from the north of England—three of these from very far north indeed—and only one is now upon the Council. The special knowledge of the others placed them upon the deputation; and we all owe them a debt of gratitude for the long journeys and loss of time they incurred in the service of the profession.

A CLINICAL MEETING.

Of late, practitioners in general have shown a welcome increase of interest in clinical records and discussions. This is evident from the contributions to professional journals, and perhaps even more so from the reports of our Societies. Several Societies now hold occasional "clinical meetings" with increasing success, but we do not remember one so successful and brimful of interest as that of the Midland Counties V.M.A., which we print this week.

This must be read to be appreciated, and all clinicians will find some portions well worth re-reading. It contains an abundant variety of clinical matter from town and country alike, all of it interesting, and some portions, as the discussion upon acorn poisoning, likely to be very helpful indeed to some of us. It has a further indirect educative value. It illustrates a truth upon which we have long insisted—that every member with an ordinary practice, if he adopts the habit of taking notes of his cases, can contribute not a little to our professional advancement.

A single clearly narrated clinical case is always interesting and instructive to some men. A series of such is often as valuable as almost any set paper, and always infinitely more so than a paper largely consisting of repetitions of text-books. That explains the deserved popularity of the "clinical meeting."

TRACHEAL PERCUSSION IN EQUINE PRACTICE.

At the time the foreign abstract under the above heading appeared in *The Veterinary Record* (Nov. 18th, p. 309), I thought that percussion of the trachea was quite a new diagnostic method, but I had not then read an article upon "Pneumonia and Pleurisy in the Horse," by Major-General (then Vet.-Major) Fred. Smith, which appeared in *The Journal of Comparative Pathology and Therapeutics* so long ago as 1897.

This paper is very largely concerned with the physical examination of the horse's chest in health and disease; and it contains a clear description of this method of simultaneous percussion of the trachea and auscultation of the chest wall. Smith prefers direct percussion with his fingers, while the Austrians use a pleximeter; that is the only real difference between them.

Smith alludes to the method under the heading of "bronchophony," which is a term employed by human physicians "to indicate the fact that the voice of the patient can be heard with undue distinctness through the chest wall." For this purpose Smith utilises, when it is available, the grunting sound which is often present in lung trouble, and says—"When the voice sound is produced by the patient grunting, the grunt may be heard over the chest wall as if it proceeded from immediately beneath the stethoscope. This is the characteristic feature of the sound; it appears to be produced in the portion of lung being examined, but of course agrees in time and sequence with the grunting, loud or suppressed, heard at the nostrils." A sentence or two later he says—"Bronchophony once heard can never be forgotten; it indicates lung consolidation, though it is often absent even when the lungs are quite solid." But when grunting is absent, Smith says that "we can artificially produce a sound in the trachea, which for all intents and purposes of diagnosis may be regarded as a voice sound produced by the animal itself." This he does "by tapping lightly on the exposed surface of the trachea high up in the neck. The tapping can be heard with the utmost distinctness, as if proceeding from under the instrument on the chest wall; to distinguish this form of bronchophony we may term it the "tracheal reflex."

Both these forms of bronchophony, Smith tells us, though indicative of lung consolidation, are often absent when that condition exists. The most probable explanation of this is that a patent condition of the bronchial tubes in the consolidated area is necessary for the production of the sound at the chest wall. Another somewhat allied sound, however, is seldom absent, viz., *pectoriloquy*. Smith

uses this term to denote the sound produced by swallowing, and heard at the chest wall by the stethoscope, of which he says—"The difference between it and bronchophony is that in the latter the sound seems to *pass away from under* the instrument, while in the former it appears to *pass up the instrument* with the most remarkable distinctness, so that if the person whispers each syllable is clearly heard." The latter portion of the sentence refers to human medicine, where a sound of this peculiar character is almost diagnostic of a cavity in the lung. Smith, however, says that a similar sound in the horse, produced by *swallowing*, is often heard in simple lung consolidation without abscess.

Smith's whole paper is worthy of most careful study from all who are concerned with equine respiratory disease. Like all this author's work, it is full of evidence of independent thinking and observation, and there is certainly very little in the English veterinary literature on this particular subject of which the same can be said.

One practical hint the paper contains may be mentioned, as I have not seen it elsewhere, and the author describes it as "one of the most valuable aids in the diagnosis of lung trouble of which I am aware." It describes the induction of a deep respiration in the horse, which Smith effects by completely closing the nostrils with one hand till the horse evidently requires air, when a deep breath will generally follow the removal of the hand. This requires some practice, as, if the nostrils are kept closed too long, coughing instead of deep inspiration results; but its discovery brings the auscultation of the equine lung much nearer that of the human one.

My present object, however, is to indicate the date at which tracheal percussion was known and practised in England. Smith was certainly practising it in 1897, and this suggests a question of priority which I cannot settle. I have never seen either of the two original articles by Wirth and Babor respectively, which supplied materials for my note. Both appeared in an Austrian veterinary journal (*Oesterreich Monatschrift f. Tierheilkunde*) last year, and I saw only summarised abstracts of them in a German one (*Berliner Tierärztliche Wochenschrift*) a few weeks ago. One of these states that Schindelka introduced tracheal percussion at the Vienna School "a few years ago," but it is not stated whether Schindelka has ever written upon the method, and the word by which "a few" is rendered in the Berlin journal is a vague one, viz., *etliche*, which means "some, several, a few, any," scarcely suggesting a period so far back as 1897. Still, it is not clear how or when Schindelka first arrived at this method of tracheal percussion; though, as he is an original worker who is well known to have given considerable attention to physical methods of diagnosis in veterinary practice, it is very probable that he devised it himself quite independently. But it is clear that an English veterinarian described the same method from his own experience, and was using it for the same purpose of detecting lung consolidation, fully fourteen years ago.

W. R. C.

FIBROLYSIN.

On July 14th, 1909, a valuable Hackney pony mare was sent to me from Jersey for treatment. She had received an injury to one of the hind fetlocks; it was much enlarged, was discharging pus, and there was considerable lameness.

I understood that the mare had been under treatment in the Island, and that the joint had been blistered twice. I put her down and opened up the sinuses, curretted them, and plugged them with Chloride of zinc in the stick form. Within a week the discharge of pus had ceased, but the enlargement was as big as ever, so I decided to try Fibrolysin.

I gave her nine injections altogether, at intervals of one day for the first five, and two days for the remaining four. Each injection was made in the gluteal muscles, the syringe being rinsed out with a weak solution of carbolic acid, but not the seat of the inoculation.

There was never the slightest swelling or any sign of constitutional disturbance, and at the end of the injections no one could have discovered where any single one had been made.

The joint gradually got smaller, and the mare sounder. I made careful measurements, and found a reduction of as nearly as possible one quarter of an inch every three days, the total reduction in circumference at the end of the treatment being two inches.

I had to keep the mare for some months after I finished treating her, and drove her regularly, and she returned to Jersey on December 21st perfectly sound.

I used no other treatment after the first plugging with the Chloride of zinc, and must therefore attribute some measure of success to the Fibrolysin, and am quite at a loss to account for "Enquirer's" unfortunate experience.

GERALD BLOXSOME, M.R.C.V.S.

Hove.

TWO CASES OF NECRO-BACILLOSIS.

In response to Mr. Gray's invitation, may I be permitted to record my small experience on the disease he so ably describes "Necro-bacillosis in the dog and cat?"

Case I.—On the 31st of May last year I was called to examine an aged Airedale terrier belonging to one of my clients. The animal was very lame in the near fore limb, which he frequently carried. On examination of the affected paw, the whole foot was found to be intensely inflamed and swollen, the swelling in fact extending half way up to the carpus was hard, and did not pit on pressure, the most severe lesions, however, were between the digits, the skin here was red, thickened and destitute of hair, and its surface was covered with pin head areas of serum-like fluid. The pad was much enlarged, probably half again its normal size, but not very sensitive, and showed no signs of slough-

ing or gangrene. In the course of a few days pustules about three-quarters of an inch long and a quarter inch deep, began to rise between the claws, which on being lanced exuded dark coloured, bloody pus, in which were freely mingled particles of necrosed tissue. The resulting wounds showed no tendency to immediate repair, and would allow a fine probe to be inserted nearly three-quarters of an inch between the skin and bones of the middle digits. The intermediate connective tissue having been broken down, no doubt by the agency of Löffler's bacillus, and eliminated in the discharge, thus forming the small fistulæ. The dog meanwhile maintained his usual health, the disease remained strictly confined to the left foot. Unfortunately no bacteriological examination was made.

Treatment.—Kept chained upon clean straw and fed on a liberal but digestible diet; at first medicated poultices and foot baths; slit up fistulæ and opened abscesses, mild caustics and free use of strong antiseptics. Unfortunately Bier's treatment was not tried, although it would have been an ideal case for that method. Internally large doses of quinine and iron. Cure complete in about five weeks, since when dog has remained healthy.

Case II.—Two-year-old male cat, moderate condition. Large necrotic area on face, size of a five shilling piece, skin hard, dry, and parchment-like, much under-run in centre but firmly adherent to healthy tissue round periphery. The surface showed several pinhead-like holes scattered throughout, giving it a sieve-like appearance, emitting dark thin pus; probably previous history of scratch on cheek.

Treatment.—Complete excision of diseased skin, and usual treatment of a poisoned wound, was followed by rapid complete recovery.

No doubt both these were cases of mixed infection, but I am led to think that Löffler's bacillus was the principal cause of the mischief in both cases.

W. WALKER, M.R.C.V.S.

Harrogate.

ABSTRACTS FROM FOREIGN JOURNALS

FRACTURE OF THE STYLO-HYOID BONE IN THE HORSE.

Desider Szathmary relates (*Allatorvosi Lapok*) a case of this unusual injury in a three-year-old mare. A smith attempted to rasp the molars; the animal struggled, struck her head against an iron ring, and since that time bled from the mouth, while her tongue hung out.

By the aid of Bayer's mouth wedge, several lacerated wounds were found upon the ventral surface of the tongue.

When drinking, the animal showed difficulty in swallowing; and the laryngeal region was very sensitive, especially upon the left side. The author now introduced his hand into the mouth, and demonstrated the existence of crepitation in the neigh-

bourhood of the palate upon the left side. This indicated fracture of the stylo-hyoid bone.

Treatment consisted in the application of Priessnitz poultices upon the laryngeal region, an alum mouth wash, and sloppy diet. In five weeks the animal recovered, she could take food without difficulty, and only by very attentive examination could it be noticed that the left half of the tongue appeared somewhat atrophied.

The author remarks that the fracture was most probably not a complete one; and, as it remained covered, the circumstances favoured an aseptic union by means of the formation of a callus. —(*Berl. Tier. Woch.*)

THE REACTION OF THE URINE OF THE DOMESTIC MAMMALS.

Hans Müller, of Kandern, has been carrying out researches upon this subject. His conclusions vary considerably from those generally accepted, and are summarised as follows:—

1. An acid reaction of the urine of carnivora is not so frequently met as has hitherto been supposed.

2. The urine of fasting carnivora is not characterised by an acid reaction.

3. The urine of carnivora assumes no constant alkaline reaction as a result of vegetable food.

4. No constant acid reaction appears in carnivorous animals upon a purely flesh diet. The reaction of the urine of carnivora is therefore not exclusively dependent upon the diet.

5. The reaction of the urine of herbivora is more easily influenced by variations in the food than that of carnivora.

6. In cystitis the urine of carnivora most frequently has an alkaline reaction.

7. As a rule the urine of herbivora has an acid reaction in severe affections of the digestive tract, and in severe pharyngitis, pneumonia, and muscular rheumatism. A catarrhal affection of the small intestine is especially likely to cause acidity of the urine. —(*Berliner Tier. Woch.*)

CURETTAGE OF THE BLADDER IN CYSTITIS.

Pasquale di Paola, of Carinola, reports (*Il Nuovo Ercolani*) that he has attempted this therapeutic measure (which was first adopted by Cumston in the case of human beings) upon dogs, and with surprising results. He recommends it particularly in obstinate cases of purulent cystitis which resist every other treatment.

The operation is performed through an abdominal incision in the median line, under narcosis. After the abdominal cavity is opened, the bladder is drawn out, covered with sterile gauze, and such urine as remains in it after previous catheterisation is expelled by light pressure directed from the fundus to the neck. The bladder is next thoroughly washed out with 3% boric acid solution. An incision of from 4-5th inch to 1 1-5th inch long is then made upon the under surface of the bladder, a sharp spoon (the author uses Recamier's model) is introduced through this, and the diseased mucous membrane is curetted—first the upper, then the

under, and finally the portion at the neck of the bladder. During the operation, and also afterwards, thorough rinsing with physiological saline solution is necessary to remove all *débris* and possible blood-clots. Hæmorrhage should be allayed by 4% antipyrin or concentrated ferripyrin solution. The vesical wound is stitched with catgut, and the peritoneum, muscles, and external skin with silk. When all requisite aseptic and antiseptic precautions are carefully observed, neither a rise of temperature nor any other unfavourable complication need be feared.

The author operated in this manner upon six dogs, in which he had artificially induced severe cystitis by irritation with purulent secretions and putrid materials. In all six cases he obtained complete recovery within periods of time ranging from 8 to 20 days,—(*Berliner Tier. Woch.*)

W. R. C.

[The fact that these cases were all artificially induced somewhat weakens the author's conclusions. Possibly the operation may prove of value as a last resort.—TRANSL.]

Royal College of Veterinary Surgeons.

FELLOWSHIP EXAMINATION.

A meeting of the Board of Examiners for this Degree was held at the College, 10 Red Lion Square, W.C., on Saturday, December 2nd. The following is a list of the successful candidates with the title of their respective Thesis:—

- R. L. PHILLIPS, "The Clinical Aspect of Infectious Pneumonia in the Horse."
A. F. CASTLE, "Sterility in the Mare."
F. J. DUNNING, "East Coast Fever, particularly as applied to South Africa (Rhodesian Redwater, or African Coast Fever)"

COAL MINES BILL.

On Thursday, November 30th, a Deputation from the Royal College of Veterinary Surgeons attended at the Home Office, in order to lay before the Chief Inspector of Mines the views of the Veterinary Profession with regard to the Clauses of the above Bill dealing with the inspection of animals in mines. The Deputation had to be very hurriedly formed, for the clauses in question had been inserted in the Bill during its passage through Committee, and the information only reached the College when the Bill was already at the Report stage. The Council was represented by Mr. F. W. Garnett, Chairman of the Parliamentary Committee, and there were also present Mr. W. Hunting, ex-President, Mr. G. Elphick, Newcastle-on-Tyne, Mr. H. Peele, Durham, Mr. W. Woods, Wigan, together with the Solicitor and Secretary of the College.

Mr. GARNETT in opening the case stated that several of the members of the Deputation were experts with regard to the inspection of animals in mines and on the testing of animals for glanders.

Section 109, Sub-Section 3 of the Bill was read, as follows:—

"The Secretary of State may appoint any fit persons to be special inspectors for the purpose of examining into the care and treatment of horses and other animals used in mines and of enforcing the provisions of this Act relating to horses and other animals, and any person appointed as a special inspector under this provision shall so far as necessary for the exercise of his powers and the performance of his duties as such inspector have the same powers as are given to and be subject to the same obligations and restrictions as inspectors of mines under the foregoing provisions of this act."

That Section, Mr. Garnett pointed out, had no doubt been drafted on Section 10 of the Third Report of the Royal Commission on Mines which runs as follows:—

".....periodical inspection should be made, once at least every six months, of every horse in every mine where there are more than 20 horses by a duly qualified Veterinary Surgeon; or, where there are less, by some person appointed in writing for that purpose; such surgeon or other person to be approved by the Inspector of Mines. Such Veterinary Surgeon or other person should examine the horses, and also the books kept by the horsekeepers and sign the same on each occasion on which he visits the mine. He should also be required to report to the management any regularities or breaches of the Act that come under his notice, and to make an entry of them in the afore-said book."

We have a high opinion of the veterinary profession and we believe that if entrusted with these duties they would perform them conscientiously and well....

Mr. GARNETT continuing, said that they submitted that the only competent man who could give an unbiased opinion under such a section as 109 (3) was a fully qualified Veterinary Surgeon. The inspection required dealt with harness and sanitation, sores, general health and upkeep of the horses, and was also to be a check on the horsekeeper. They suggested that the words "fit person" in the section should be altered to "fully qualified Veterinary Surgeon".

Passing on to the Third Schedule of the Bill, Mr. Garnett referred to the first Clause which reads:

1. No horse shall be taken underground until it is four years old and until it has been tested by a competent person with the prescribed test and certified to be free from glanders."

The words "competent person" require to be altered. Only qualified Veterinary Surgeons could be said to be the "competent person" to perform the test, and it was also desirable that the test should be specified as the Mallein Test. That only Veterinary Surgeons should be employed for such purpose was a principle recognised by all bodies having the control of animals, e.g., the London County Council, the Board of Agriculture, etc. The test was a most delicate one, depending for its diagnostic value upon a knowledge and appreciation of the bodily health of the animal at the time of testing and the conditions under which the animal was living. There was the local reaction to be observed and the thermal reaction. They strongly submitted that these serum tests could only be effectively applied by fully qualified men.

Mr. HUNTING said he supposed it was not necessary to insist on the importance of keeping glanders out of the mines. It was dangerous not only to the animals but also to human beings. He had heard it said that there are only two or three deaths per annum from glanders, but the medical profession had recently found that a proportion of glanders cases were not properly diagnosed as such. There were probably 20 or 30 deaths from glanders per annum, making a very serious addition to the list of preventable diseases. He also emphasised the point as to the difficulty of taking the mallein test. In London twenty or thirty thousand horses had been tested

with mallein by expert Inspectors, Veterinary Surgeons. Even they had made mistakes in fifteen instances. In reply to a question by the Chief Inspector, Mr. Hunting described the method of taking the test, and urged that a horsekeeper could most certainly not be said to be a competent person to administer the test.

Mr. PEELE pointed out that the sale of mallein and of hypodermic syringes was absolutely uncontrolled. Anyone could buy them, and it was within the power of anyone to get a vague idea of how to apply the test and what to look for. But a man with half knowledge was liable, nay almost bound, to get a false result. Even supposing that the wording of the Schedule were left as it was, and that an incompetent person took the test and got what he considered to be a reaction, he would be bound under the Glanders Order to report the matter, with the result that the Veterinary Inspector would have to be called in and the whole process gone over again. This would cause unnecessary pain to the animal, and danger both to the horses and to human beings.

Mr. Woods expressed the opinion that it would be a useful thing in the first instance to describe the necessary test in the Schedule as the Mallein test. There were two other tests which were considered to be good tests by bacteriologists, but which were impracticable except in a bacteriological laboratory. He described the mallein test and emphasised the importance of it being carried out by properly qualified persons. It was essential that the words "Competent person" in the first Clause should be defined, as a definition of these same words was given later on as "Horsekeeper."

There was another important point. They might now have glanders down the pits. There was an immense number of Russian ponies used down collieries in this country, and Russia was a hotbed of glanders. It was quite possible there was glanders in the pits at the present time in a latent stage which might go on for months. The tested ponies might therefore be sent down into an infected place. It was necessary if the Act was to be effective that the whole of the ponies at present in the pits should be tested.

Mr. REDMAYNE, the Chief Inspector, stated that with regard to the mallein test, the Clause spoke of the "Prescribed" test which he held to mean "Prescribed" by the Secretary of State, and he did not hesitate to say that the Secretary of State would follow the best advice and that the test he would prescribe would be the mallein test, failing the discovery of a better. He thought the views of the deputation on that point were met in that way. With regard to the "competent person" he saw the point of the deputation that the words should be defined. As it was, however, if an incompetent person were employed and any accident ensued, then the managers or whoever else allowed that incompetent person to be employed, would have committed a breach of the Act.

The SOLICITOR pointed out that it would be better to define the words. There would then be no such difficulty.

The CHIEF INSPECTOR said he quite agreed that the words competent person did not necessarily mean a professional man, and he would certainly put the views of the deputation forward. He could not say more or less.

Mr. ELPHICK endorsed what had been said by the other members. He pointed out that in the Army, Farrier-Sergeants or Farrier-Majors were not allowed to apply the test, though they had been specially trained to look after horses. Veterinary surgeons were always employed. He also contended that no ponies should be allowed to go down the pit until they were thoroughly trained. They should be kept at least 14 days isolated and trained. This would prevent many accidents happening.

The CHIEF INSPECTOR said that he had made a careful note of all points raised and he would put them before the Secretary of State and Mr. Masterman who was in charge of the Bill. He would put their arguments as well as he was able, and of course their opinion on a matter like this was of very great value. As to the mallein test they could rest assured that the test prescribed would be the mallein test until some other better test was found. He would put the arguments in favour of specifying who was a "competent person." He could not say whether or not the Secretary of State would accept that.

The deputation then withdrew.

MIDLAND COUNTIES' VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held at the G and Hotel Leicester, on Thursday, Nov. 9th, the President, Mr. H. L. Pemberton, of Bridgnorth, occupying the chair. There were also present: Messrs. Evershed, Nottingham; F. J. Taylor, Moseley; E. W. Parkes, T. Bainbridge, Wellingborough; D. Forwell, Towcester; W. E. Ison, Atherstone; T. G. Parr, T. H. Ho son, Leicester; W. T. Brookes, Warwick; H. Yeomans, Kidderminster; H. S. Reynolds, Daventry; R. H. Over, Rugby; W. N. Thompson, Derby; F. L. Goch, Stamford; J. A. Gold, Redditch; J. J. Burchnall, Barrow-on-Soar; W. H. Brooke, Handsworth; R. H. Phillips, Loughborough; and the Hon. Secretary, Mr. H. J. Dawes, of West Bromwich.

Apologies for unavoidable absence were received from the following: Sir John McFadyen, Profs. McCall, Hobday, Macqueen, Dewar, Dr. Manley, Dr. Gilbert Barling; Messrs. R. C. Trigger, J. W. Coe, F. W. Barling, E. Woodcock, T. Chambers, W. Blunsom, C. M. Barton, E. Ringer, O. Hills, John Blakeway, James Blakeway, J. R. Carless, J. Deville, W. Grasby, S. M. Woodward, Brennan DeVine, John Malcolm, R. Hughes, W. Thackeray, E. J. Burndred, L. W. Heelis, W. Dale, G. Wartnaby, A. Crofts, S. Marriott, W. Tart, W. Brown, R. Cockburn, T. Spencer, J. M. Parker, C. E. Dayns, and others.

The circular convening the meeting was read, and the minutes of the last meeting were read and confirmed.

Mr. RALPH L. C. FORREST, of Alcester, Warwickshire, and Mr. G. THORNTON, of Leicester, were nominated for membership, their names to be submitted for election at the next meeting.

Mr. B. L. SECKER, of Malvern Link, was elected a member of the Association, on the proposition of the Hon. Sec. (acting for Mr. F. W. Barling) seconded by Mr. Gold.

The HON. TREASURER (Mr. Burchnall) reported the resignation of Mr. J. H. Barber, of Alcester, who had sold his practice and left the district. The resignation was accepted with regret.

RECOMMENDATIONS OF COUNCIL.

The following minutes of business transacted by the Council of the Association prior to the general meeting were submitted and approved:

A letter dated from the Royal (Dick) Veterinary College, Edinburgh, was read *re* the amalgamation of societies, and announcing that the amended rules had been passed by the National Veterinary Association.

A notification was received from the Royal Sanitary Institute that the next Congress will be held at York in August next, and the Hon. Sec. was requested to bring the matter before the February meeting.

It was reported that Prof. Bradley had kindly promised to lecture at the next meeting on the subject of Heredity.

The Hon. Treasurer reported that there were six members in arrear with subscriptions, three owing five years and three owing three, and the Council recommended that the Hon. Sec. be instructed to write to them and inform them that unless their subscriptions be paid before the annual meeting in February their names will be publicly read out at that meeting and they will be struck off the membership roll.

The annual meeting was fixed to be held in Birmingham.

CLINICAL NOTES.

A CASE OF EQUINE SARCOMA.

Mr. W. H. BROOKE. The two cases, he thought, would be of interest because members of the profession met with such a number of things they were apt to attribute to indigestion. They could not see very much further, and post-mortems in cases of this sort were helpful. The first was one of sarcoma affecting a well bred brown carriage gelding, 16 hands and 14 years old. For six months it had been doing very badly—the appetite precarious and with symptoms of indigestion. About midway through this six months period the bowels began to be relaxed, and during the latter part of the time they were very much so—at last quite liquid. The general sanitary arrangements were satisfactory. The teeth were found irregular but this could not by any means account for all the trouble. He used anodynes, astringents, and tonics, but they gave only temporary relief. There was a slight rise of temperature, varying between 100 to 103 and 103 degrees. Hepatic symptoms were absent. The animal was feeding fairly, but the appetite failed in latter part of the time, and the animal gradually wasted, and as the bowels began to be more relaxed he concluded there was serious obstruction in the lymphatic glands. He thought it might be tuberculosis, and applied the tuberculin test with negative results. The patient got worse and worse, and was destroyed. A post-mortem was made, and the small intestines were found to be a third of the normal calibre, while the large bowel was only about half the usual calibre. There was great distension of the veins, and the slightest touch with a knife caused hemorrhage. About two feet from the termination of the ileum there was a tumour weighing 4lb, and affecting the glands on the large bowel. Most remarkable was the condition of the sublumbar glands. When cut out of the loins and put on the scale the enlargement weighed 40lb. He had never seen a tumour of that description weighing that amount.

TUBERCULOSIS.

The second case was a grey cart gelding, 12 years old. He had examined it three or four years before, and it had always kept up well in flesh. It had a slight cold, and its appetite was precarious, refusing large feeds, but feeding fairly. The symptoms pointed to digestive derangement. The animal was looked after for a week and improved, but then steadily got worse. The bowels became inactive, and for a week or ten days before death, unless kept relieved with enemas, there was no action. Hard pellets filled the rectum. Examination per rectum did not disclose anything distinctive. There were occasional blowing fits with normal intervals. He looked on the bowels as the seat of the trouble, but could not understand it altogether. The gelding gradually lost in flesh. The tuberculin test gave negative results. During the last few days the lungs were seriously involved, and on the day of death the symptoms were very urgent, with profuse perspiration, and the bowels seemed very relaxed. The post-mortem showed general congestion of the bowels, especially of the small intestine, and there were tumour-like enlargements affecting the sublumbar glands and the spleen, which when cut into were calcareous. There was very little pus, and

it was evidently of old standing, but there was a sudden affection of the lungs, no doubt due to the giving way of one of the lymphatic glands. The bronchial glands were similarly affected, and the lungs were the seat of dense tuberculosis.

In reply to Mr. Over, Mr. Brooke stated that the sublumbar glands were a good distance forward.

Mr. GOLD, referring to the first case mentioned by Mr. Brooke, asked whether he satisfied himself that the remarkable growth was typical of sarcoma? Apparently the second horse had been suffering from tuberculosis for a long period. Was the diarrhoea precedent or subsequent to the tuberculin test?

Mr. BROOKE replied that in the case of sarcoma he found it first, and Mr. Malcolm confirmed it. The diarrhoea occurred after the test in the second case.

ACORN POISONING.

Mr. W. T. BROOKES followed with "Some Notes on Acorn Poisoning, as met with in Cattle." He said: During October I was called in to several lots of cattle in different districts suffering from acorn poisoning. The first lot of young cattle were taken ill on the 9th of October, and consisted of nearly all heifers, Shorthorns and Herefords, about 18 months to two years old. Eight animals were affected. One of them died on October 14th, and another on October 21st. On this date the remaining six had recovered and commenced feeding again.

The second lot of young cattle were situated in another district altogether, and were all heifers. They were taken ill on October 16th, and one was found dead on arrival. Eight other heifers were found to be suffering from undoubted acorn poisoning, and two of them were already *in extremis*; one of them died on the night of the 16th of October, and the other on the 17th of October. On October 18th three of the original eight were well, and three fresh cases had occurred, making in all 11 cases. On October 21st the remaining eight heifers had all recovered.

Several other beasts in different parts have come under my notice, making 30 in all, nine of which have died. Most of the symptoms described in any text-book I have been able to refer to have been conspicuous by their absence. The chief things noticeable were the dull and depressed appearance of the animals, an entire absence of appetite and rumination, a weak, feeble pulse, subnormal temperature, and a disinclination to move about. Only one case in the first group and two in the second showed a mucous and blood-tinged discharge from the nostrils and anus. These all died, the first eight days after being seen, and the other two the day afterwards. An obstinate stoppage was noticeable in all the cases, and what little faeces were passed were inky black, stinking, and very thick. This impaction did not yield at all easily to treatment, and where a post-mortem was made, the acorns were still present in the stomach.

In treatment, oleaginous and saline purgatives were given, combined with aloes Barb. in solution up to 5viii, and Croton oil. Alkalies, as Soda and Pot. carb. were given, as well as stimulants—Nux vomica, Ammon. carb., Spt. aeth. nit., and Spt. ammon. aromat. Also linseed and oatmeal gruels. In one case a drench consisting of Aloes Barb. ʒi. in solution, Croton oil 40℥, Oleum. lini. Oiss. was given.

The post-mortem examination showed all these were more or less alike. The rumen contained an enormous quantity of pulsatous material—of gruel, and food which apparently was not able to pass on through the second and third stomachs, also acorns and acorn husks. The mucous membrane was congested with numerous hæmorrhagic spots noticeable. The reticulum was normal. The omasum was somewhat empty, the contents of a pasty consistence. This organ had the appear-

ance of being partially paralysed, was more or less collapsed, and seemed to act as a trap through which neither food nor gruel could pass. A patchy congestion was noticeable. The abomasum was intensely inflamed throughout. The spleen was normal in size but had a curious congested appearance in sections. The small intestines showed occlusion of the bile duct, were not very full, and contained inky black fluid material. The mucous membrane was more or less inflamed, and in some cases the contents of this bowel were blood tinged.

The liver was nearly always pale and congested with bile. The gall bladder was four times its normal size. The kidneys were very pale, and dropsical fluid was present in the fatty envelopes. In the case of the lungs, ingesta was found to have gained entrance through the trachea in two cases, and the lungs themselves were intensely congested. Through the occlusion of the bile duct, the portal system appeared to have been disorganised, and as a result all the organs of the body were congested. The stomachs appeared to have lost all tone and to be partially paralysed, and the omasum seemed to have acted as a trap through which neither food, gruel, nor medicine could pass. The rumen consequently became tremendously dilated, and the acorns remained in the stomach instead of being passed on. As a result of this condition of the rumen, regurgitation of the food took place, and some of it was got down into the trachea.

These very inadequate remarks have been written with the hope of creating a discussion amongst the members, and I shall be very grateful for any information on the subject. I must confess I have found acorn poisoning a most difficult ailment to treat, and have often thought of resorting to inter-tracheal injections of eserine, but have never quite liked to attempt it. I shall be greatly obliged if any of you will suggest a new and more successful treatment than the mere administering of medicines.

Mr. YEOMANS contributed a note on the same subject. During the last month or six weeks, he remarked, practitioners in districts where oak trees were found had had many cases of acorn poisoning in cattle. In his experience the symptoms in most cases had been as follows: The animal seemed heavy, depressed, and listless, with loss of appetite and cud; there was constipation, a doughy condition of the rumen on palpation, and grunts. In fact the symptoms were those of acute digestive disturbance. Later on the eyes had a sunken appearance, diarrhoea set in, the faeces being dark coloured, offensive, and blood stained. The temperature at first was normal, and later sub-normal, and in fatal cases death took place in from about three to seven days.

Judging by the report of the number of deaths that had occurred recently, the treatment up to the present had not been so satisfactory as they could wish. He knew of no specific antidote, and his only reason for bringing the subject forward was that he hoped to gain some information from the discussion. The best results had been obtained by the early administration of a fairly large saline aperient combined with vegetable bitters, and followed by ant-acids, stimulants, etc., demulcent and nutrient drinks such as boiled linseed, new milk, etc. It certainly did seem that in those cases where the aperient was given early, the results were much better than when the practitioner was called in later on, as was too often the case.

Mr. GOOCH commenting on these two papers, inquired what was the actual cause of death in cases of acorn poisoning; and whether it had frequently been found that death had resulted after cattle had been removed for at least three weeks from places where acorns were to be found? He had had fatal cases in which the cattle had been feeding probably three or four weeks before on acorns, and then acorn poisoning had set in.

Every time one of the first symptoms had been black diarrhoea. He had had large experience this year, much more he hoped than he would have again, of fatal cases, and he had found that practically no treatment was of any avail after a certain stage. If the animal was depressed, with subnormal temperature, he had not known a recovery. In the only one in which recovery had taken place no medicines were administered; the animal was simply fed up.

Mr. BROOKES took it that the actual cause of death was the absorption of the toxin from the acorns.

Mr. GOLD remarked that all those members who practised in agricultural districts had seen a lot of what was called acorn poisoning this season, and the symptoms that had already been described were very much the same as in the cases that had come under his notice. What was noticeable in the later stages was that there was loss of control of the limbs. Mr. Brooks did not say anything about large clots of blood passing from some cattle. A remarkable feature in connection with Mr. Brookes' post-mortems was what might be called the dropsical condition of the kidneys, and the situation of the whole of the disease at the rear of the kidneys. A lot of trouble was experienced in getting rid of an enormous quantity of fluid from around the kidneys and loins. Another peculiarity was the corrugated condition of the large bowel. In illustration of this, Mr. Gold produced a specimen, out of a Shetland pony, the state of which, he suggested, showed that recovery was out of the question. In bullocks he had noticed that when they had been suffering from the disease for some days there was a dropsical condition of the sheath. He had never yet known a case of that description in which the animal had recovered. He was afraid that at the stage at which veterinary surgeons were called in they had not much to say about treatment. He did not know of anything heroic that was much good.

Mr. BROOKE, observing that if they did not really know what they had to treat they were not likely to treat it successfully, suggested that in these cases it was tannin poisoning that limited absorption. Tannin was an antidote to a number of alkaloidal poisons. He took it that the trouble lay in the limiting of the absorption. The condition of the fat around the kidneys he thought was due to lymphatic obstruction. He should like to hear more as to what the post-mortem showed to be the condition of the gall bladder.

Mr. PARKES asked whether it was not an accepted fact that the cause of death was tannin poisoning, and Mr. GOOCH said he should very much doubt it.

Mr. FORWELL thought the period before death occurred was much shorter than had been stated. He had had a case in which it occurred in less than three days. It was not blown up.

Mr. ISON said he had seen several cases in which the animal had got blown up through eating acorns and had died. He concluded that that was not acorn poisoning. As to treatment, he suggested plenty of linseed gruel, and he had also great faith in treacle. Was the action of the acorns such as to cause a large secretion of bile?

Mr. BAINBRIDGE mentioned that in a case which he was attending he had given doses of Epsom salts with some bi-carbonate of soda. He was somewhat ignorant as to the treatment, and whether in this instance it would prove effectual he did not know. In another animal the faeces were very black and there was an oozing of blood from the nostril.

The PRESIDENT stated that acorn poisoning was extremely prevalent in his district. A remarkable case was that of a cow that had been running with a calf in a park. When he was summoned he found her down and unconscious, with her nose pushed into the ground. She had been given a pound of salts, and he gave her a good dose of linseed oil, about a pint and a half, and

some bicarbonate of potash. The next morning she ran him clean out of the place, and she was now getting well. A free passage had been obtained with the bowels, particularly open and natural. In two other cases he at first gave a pound of salts mixed with a pint to a pint and a half of oil, and the animals were recovering. If the trouble was taken in hand early satisfactory results could be secured, but if the acorns had been eaten for from a fortnight to three weeks it was a difficult matter. He had a case in which a cow had not been near an acorn for a month and yet she was ill. The bowels were relieved, and he administered vegetable tonics and stimulants and persevered with bicarbonate of soda. A peculiar case was one in which the owner had given salts, linseed oil, fat bacon, and butter to get the animal's bowels open. He (the speaker) then gave simple tonics and stimulants and the animal was now going on all right.

The HON. SEC said it seemed to him that after all the attention which had been drawn to acorn poisoning by the daily papers, farmers did not take sufficient care to keep their animals from oak trees. He thought the County Councils might with advantage issue leaflets drawing attention to the danger.

Mr. PARKS asked whether cases of acorn poisoning in sheep had come to notice.

The PRESIDENT said he had never known that they were killed by acorns, but a bailiff once told him that on opening two lambs that had died he had found a quart of whole acorns. Answering a similar question as to pigs, the President stated that he had a case in which a pig steyed up was blue all over, and he found that the owner had given it acorns, which in his opinion had caused the blueness.

Mr. TAYLOR pointed out that acorns were sometimes ground up and mixed with corn, and the President replied that given in moderation it was splendid food. If animals were given a liberal supply of hay when acorns were about they were not poisoned by the latter.

Mr. YEOMANS said he had used treacle very extensively, especially in the early stages, and had found it very beneficial. Had any member used barium chloride? With reference to the case in which death occurred within a few hours, he did not think the acorns had been eaten a sufficient time for the absorption to have caused death.

Mr. BROOKES, in answer to Mr. Gooch, said that in the cases under his notice most of the animals lingered several days, and as far as he could gather all of them had very recently eaten the acorns, and their illness was noticed immediately it occurred. He had always held the view that death was due more or less to some poisonous property of the acorn, but exactly what that was he did not know. In one instance it seemed to narcotise the animal very much. As to Mr. Gold's question, he had noticed a loss of power in the hind limbs in one or two cases, but not in all. The animals could walk about if they were compelled to, but in two or three cases, especially in those that proved fatal, they became weaker day by day, and lay down never to get up again. He had had no cases in which large clots of blood had been passed. With regard to the dropsical condition of the kidney he had had two cases in which they were practically disintegrated and black in colour. The peculiar corrugated condition of the large bowel to which attention had been drawn by Mr. Gold, had never come under his notice. He believed that the chief action of the tannin was of a constipatory nature, and the cause of the gall bladder being full was that the matter was unable to get away through the small intestine. He had not administered oil and salts together, but had given them separately, and followed them up with doses of aloes and with croton oil. He had not, however, had very good results from whatever he had been able to give. He had had no actual case of a sheep

being poisoned by acorns, but he knew of several in which they had died from acorn poisoning.

Mr. C. E. DAYUS (Craven Arms) who was to have read notes on "Bracken poisoning in cattle," was unfortunately unable to attend.

COWS AND WALNUT TREES.

Mr. GOLD. On October 8th, he was requested to see three cows; the animals were re-testers in a clean herd of 100 dairy cows, and they yielded to treatment much more quickly than in cases of acorn poisoning. He found the animals to be showing the following symptoms: very dull in appearance, eyes very blood-shot, constipated bowels, champing of jaws, frothy saliva around mouth, and occasionally grinding teeth. When made to get up they appeared quite silly, and blundered about the yard and building, falling over, and showing symptoms of epilepsy. If left alone they lie quietly, but there was continued champing of jaws and twitching of eyes. One cow passed a little dung which was hard and covered with blood, and showed every condition of paralysis of the bowels. Water was passed in very small quantities, and of a light blood colour. The whole of the cows strained after passing water, and this continued for about two days more or less. The cows had been turned out in an orchard which contained fruit trees—apples and pears—and also several walnut trees. The branches of three or four of these were low and within easy reach of the cows. Two of the cows were dry and lying off calving, and having one or two feeds per day, the same as ordinary cows. The third, a barren cow, was dry also. The cows were noticed to be eating not only at the branches and leaves of the walnut trees, but also the nuts and huds. The symptoms were certainly those of a form of narcosis. He was quite at a loss to know what the poison was in walnuts, and was still in the same uncertain state. The cows responded to treatment in the course of a few days, and as far as could be seen had made a perfect recovery. He would like to hear if any member had had a similar experience, and if so, was he able to detect the poison contained in walnuts, huds and leaves.

Mr. Gold explained that he gave a good strong purgative in the first instance, consisting of salts and aloes, and followed up with the usual digestives, nux vomica, ammonia, and things of that sort. Except for what they obtained in the orchard, the three cows were fed in exactly the same way as from 95 to 115 others on the premises. The cows could have got nothing else but apples, pears, and the walnut trees, apart of course from the grass. He was strongly of opinion their condition was due to their having eaten walnuts. There had been a serious outbreak of swine fever a few months before, but the later trouble could not be connected with that.

A FEW CANINE MOTOR ACCIDENTS.

Mr. F. J. TAYLOR (Birmingham) said: No doubt many of the members present practise in districts where motor cars are "occasionally" seen in the streets, and they invariably have a casualty list to account for in the shape of dogs, a great number of which are rolled over and over under the chassis and come out at the other end simply shaken, frightened and covered with dust, whereas others suffer from injuries so remarkable, and so unlike other injuries, that I thought a few cases of this nature might be interesting to those canine practitioners in large towns, where motor cars frequently bring in a little grist on the one hand to compensate for the financial loss they cause to our business on the other hand.

Correct diagnosis on the spot is often an impossibility owing to the complex nature of the symptoms presented immediately after the accident. The usual history is

that owner was exercising his dog which strayed into the road, and a motor coming along at quite a regardless speed, alarms the owner, who calls the dog, and in this way distracts his attention for the moment from the car. The driver of the car trusts that the dog may obey his master and proceeds, but the dog remains stationary. The result is an almost unavoidable collision, in which the starting handle, radiator, ends of the springs, tyres, or the chassis play an important part, and the victim is extremely lucky to come out at the other end (as frequently happens) simply very dirty, bruised, and frightened. On the other hand, more serious consequences may ensue, as the following instances will illustrate:

I. A wolf hound, after collision with a large car, was run over by both near side wheels without any external injuries being inflicted. It was brought to me in a totally paralysed condition, being unable to move any limb, and having quite lost the powers of retention. He remained in this condition for five days, being artificially fed. Catheters and enemas were used three times daily, counter irritants were applied to the spine, and iodide of potass and strychnine administered internally. Complete recovery took place from the sixth day.

II. An Irish terrier jumped from a car in motion, which ran over him with one wheel. When seen the dog was evidently in acute pain, and difficult to handle, great tenderness being manifested on manipulation of the posterior ribs. There was no external injury to assist in the diagnosis. Anodyne liniment was applied, and internal sedatives given, but the dog died during the night. The post-mortem showed a rupture of the capsule of the spleen and an exudation of the contents into the abdominal cavity, the border of the interior right lobe of the liver was split in seven places, and the duodenum almost completely severed by the crushing action between the tyre and possibly some rib-like elevation in the road.

III. A collie dog was completely run over by a chassis, and in the rolling process both testicles and scrotum were nearly torn away, and damage to some surrounding tissues necessitated removal of the former. No complications ensued, and recovery rapidly took place. I mention this case, which may seem a somewhat trivial one on the face of it, because of the frequency with which this class of injury is inflicted by motor cars, and I attribute it to the fact that during the rolling over which takes place underneath the car, the testicles, being pendulous, are liable to come into contact with projecting metal parts, and become badly torn or completely removed by being hooked up in some way.

IV. A Dalmation bitch, which was run over by one wheel, showed no definite symptoms for twelve hours, when she began to look distressed, and breathing became accelerated. No urine having been passed during the night, a catheter was used without success. Great pain was evident in the perineal region, which hot fomentations seemed to increase, and death took place 24 hours after the accident. The post-mortem revealed a ruptured bladder and peritonitis. I blame myself for not operating in this instance, as I was firmly convinced at the 12th hour that such a possibility might exist, but the owner was averse to operation, and I was unable to convince her of the evident necessity. I should not hesitate, however, when permission can be obtained, to open the abdominal cavity whenever internal injuries, or organic ruptures can be diagnosed, as my next case will substantiate.

V. A fox terrier bitch, ten years old, after an accident in the street, was seen in a collapsed condition, and evidently bleeding profusely internally. There was no relief from the treatment adopted, and it was decided to operate the same night. Rupture of the right kidney was found, and on this being ligatured and removed, the hæmorrhage ceased. The abdominal cavity was washed

out with a normal antiseptic solution and mopped dry with sterilised gauze and wool. The wound was closed in two layers by gut and silk, and there was a complete recovery in a few days.

VI. A retriever dog was brought in with prolapse of the bowel and external wounds in the thigh and inguinal region after an accident with a motor cycle. The operation of protopexia, or ventrifixation of the bowel to the abdominal wall was performed with good result.

VII. A young terrier dog was injured in the lumbar region and kidneys by a car. It died an hour after being seen, and the post-mortem showed a rupture of the kidney and a fracture of the spine.

VIII. A cross-bred collie bitch had both fore legs fractured by a motor bicycle collision, they were set and a recovery took place.

IX. A terrier dog sustained an injury to the neck by a wheel passing over it. It was brought in unconscious, the eyeballs were rotating, and it was involuntarily passing urine. It remained in a comatose state for 24 hours and then died. The post-mortem showed dislocation of the occipito-atloid articulation, the spinal cord was almost severed, but all the other organs were normal.

X. A dog was injured by a collision with a motor bicycle, the rider of which was of opinion that the dog got his leg through the spokes in some way, with the result that the gastrocnemius tendon was completely divided in the near hind leg. Suture of the divided tendon was made under an anaesthetic, silk worm gut being used to make the union, the wound in this case being dressed with chloroform and iodine 1%, and the leg encased in normal position by plaster of Paris bandages. These remained on for three weeks, and on being removed the tendon had resumed its proper function, and lameness cannot now be detected in the limb.

XI. Partial and complete rupture of the stomach are not frequent sequels to motor accidents in my experience, but one case is worth recording in which laparotomy was performed, and a necrosed partially ruptured portion of the stomach wall was excised and the patient is still alive, apparently healthy, and free from gastric trouble.

XII. Stricture of the bowel was caused in a spaniel bitch by a motor accident, eighteen months previous to my treating her for complete stoppage and intestinal paralysis. I attempted to evacuate the bowel with glycerine suppositories, by enemas, and by a long bone spoon which I employ for this purpose, but without successful result in this instance. Laparotomy was performed under an anaesthetic, and an attempt was made to knead the obstruction down the bowel towards the rectum. This also failed, and the constricted portion of the bowel and also the obstruction were removed. The divided parts were brought together by a Murphy button, which remained in position so long that a secondary operation had to be performed to remove it from a mass of granulations and anastomosed tissue. The opposing sections of the bowel were again brought together over a tube of carrot, and this supported the united action for several days when it was passed in a partially digested condition and covered with mucus. Benger's food was given for a fortnight afterwards, and the dog recovered and is still alive.

Mr. GOOCH asked whether Mr. Taylor had had a case in which a dog, rushing straight at a car had had an eye knocked out and left lying on the cheek.

Mr. TAYLOR replied that he did not think it was a common occurrence for the eyes to be injured in accidents of this kind. Unless it was a dog with prominent eyeballs, the eye usually sank into the socket from the blow and was practically uninjured.

STIFLE DISEASE IN FOXHOUNDS.

Mr. F. L. GOOCH. Two specimens of bones, one

showing a limb that was perfectly healthy, and the other in which it was diseased. The injury was said to be due to the hound jumping a piece of timber, and he thought in that event there might be luxation of the patella. He had been under the impression that they must not look to external injury for the disease, but that it was internal, and might probably be congenital, or ascribable to rheumatism. He believed that treatment, to be effective, must take place when the animal was a puppy.

Mr. Gooch also produced a calculus which he had found tightly lodged in the rectum of a cart mare. He could reach it with two fingers, but found it impossible to remove it, and the animal died.

Mr. GOLD wanted to know whether Mr. Gooch attributed the condition of the foxhounds to rheumatoid arthritis or to some inherited cause other than rheumatism, whether it was a young puppy or an aged hound, and what was the condition of the liver?

Mr. GOOCH. The foxhound trouble was of the nature of rheumatoid arthritis. The animal was a fourth season bitch, and when she started to run she was very lame, but when she got fairly warm the lameness was not noticeable.

Formation of calculi commonly occurred in mill horses. He had had larger specimens than the one produced, but the remarkable fact concerning this one was the fact that it was impossible to remove it.

INTESTINAL DISTURBANCE IN A BULL.

Mr. D. FORWELL. On September 7th I was asked to go to see a three-year-old polled Angus bull. The owner noticing the previous day that the animal was dull and loose in his bowels thought he wanted a dose of physic, and gave him the usual pint of linseed oil.

On my arrival I found the animal looking very dull, his eyes sunken, refusing all food, but the temperature was normal and the bowels very loose. From my examination I thought he had picked up something in his food or drinking water to upset him, but was told he only had cake, hay, and bran, and he had never been out farther than the yard for drinking water. As he had a laxative in the form of the linseed oil the previous day, I gave him some tonic astringent powders composed of Ferri. carb., alum, and cascarrilla twice daily, but these had little or no effect. As he was willing to drink I gave him cotton cake gruel only. I saw him two days later (September 9th) and there was still no improvement, as the animal was still refusing food and drinking the cake gruel only. I again called two days later (September 11th) and was told he had died about an hour before my arrival.

Post-mortem, I found all the organs of the body in a normal condition, with no trace of tuberculosis or inflammation, but I was surprised to find that the rumen and other stomachs contained a large amount of ingesta in a soft and moist condition. The animal had eaten nothing, and had only been allowed gruel to drink for five days, and yet the stomachs were quite full. I was quite unable to account for this, and could only give my opinion that the bull drank some dirty water while out in the yard. But even then, why should the liquids pass through the bowels and leave the solids normal in the stomachs? I shall be pleased to have a more satisfactory solution of this case.

UNEXPLAINED SWELLINGS IN A HEIFER.

Mr. FORWELL. I examined a two-year-old short horn heifer about three months ago, by request of the owner, and found there was a long, hard, flat swelling on her back, reaching from the middle of her back to near the tail on both sides of the spine. I thought she might have been injured or possibly stung, but could find no marks. I gave some strong liniment to rub on the swelling twice daily, thinking I might get a proper abscess formation. In about a week I tried to lance in

one part, but could only get a small quantity of serum and pus evacuated. I then applied a good blister along the greater part of the swelling, but with no success, as the substance remained as hard as ever. The heifer was eating and gaining in condition, so we turned her out and let her take her chance. On going to this farm again about three weeks ago I was surprised to find that both the hind legs were swollen and hard, and the swelling on the back still present if not quite so extensive. These swellings are very hard but not painful in any way, and, as already mentioned, the animal feeds and does very well. I might mention that there are no fissures on any of the joints of the legs. I should have tried a course of Pot. iodide, but the owner was unwilling to go to further expense, and the heifer is still doing very well.

Mr. GOLD said he was not at all surprised that the stomachs of the bull were full, because it seemed to be a positive fact that an animal might be what he might term "starved" to death, and yet on a post-mortem being made a great quantity of food will be found in the rumen which it had been unable to make use of. It might have been a case of nervous paralysis of the bowels.

PARTIAL OCCLUSION OF VAGINA.

Mr. REYNOLDS explained a case of partial occlusion of the vagina. The mare was half-bred and three years old. The owner had lent her to a farmer who subsequently told him she was ill, and on going to the farm he found her with a foal half delivered, this being the first that was known of her being in foal. There was some difficulty in removing the foal, and a veterinary surgeon was sent for. Subsequently she was brought to Mr. Reynolds owing to her inability to urinate. The whole of the hair on both sides was excoriated. On making an examination he was able to put his fingers into the lips of the vagina, but no farther. At the top of the vagina he could get one finger through a small opening. He split the vagina in order to admit his arm, and found an accumulation of urine, which was gritty. The vagina had since been kept open by inserting the arm smeared with ointment, and no further trouble had been experienced. He had never heard or read of a similar case. The opening was but one little hole.

INTUSSUSCEPTION IN A FOAL.

On Sept. 26th a Shire foal had been sent to a sale, and had had an attack of colic, for which it was treated. It was brought home, and on the following day was weaned. For a considerable time it did badly, but this was believed to be owing to its having just been weaned. On October 19th Mr. Reynolds was called in, and on examining the foal could find no symptoms of pain. The bowels were a little relaxed, and the animal ate anything that was given to it. He arrived at the conclusion that it was a case of intestinal trouble from worms. Everything was done, but death occurred on Nov. 1st. He was asked to make a post-mortem, and he found that there was intussusception of the cecum, and the portion that was invaginated was solid. The foal had never shown any abdominal pain nor any sign of enteritis. He took it that the intussusception occurred on the day the animal was seized with colic.

Mr. Reynolds produced a fractured sacrum taken from a horse that sustained the injury in jumping a fence.

Also the larynx of another horse which previous to the operation thereon was a rank roarer, but afterwards gave no sign of that trouble when lunged, and made only a slight noise of that description when ridden. This animal had to be destroyed 12 months after the operation owing to lameness.

Mr. OVER mentioned that he treated the foal to which Mr. Reynolds had referred, and it was not an ordinary

case of colic. The animal was in acute pain, but at night it began to improve. It had travelled eight miles to the sale, and he regarded it as a little bit "overdone." He treated it with sedatives, a little oil, etc.

NASAL POLYPI: NECROSSED BONE.

Mr. W. N. THOMPSON: The subject, an aged black gelding of the light vanner type, was sent into hospital on January 28th last because he made a noise when at work, which was found to be due to the presence of polypi in the near nostril. Two were removed by my colleague, Mr. S. R. Robson, M.R.C.V.S. When my attention was called to the case the animal was making a noise when at rest. There was a fetid discharge from the nostril, the animal presented an unthrifty appearance, and was said to be losing flesh. An examination revealed the presence of more polypi, and necrosis of the bone was suspected. It was decided to open the nasal meatus. A hole was trephined on a level with the inner canthus of the eye and about an inch from the median line, another three inches below, and the bone between them removed by the use of the saw used in Smith's operation in feet. When this had been accomplished more polypi were seen, and it became necessary to remove more bone. This was done by the same means as before, about three inches more being removed longitudinally. We now had an opening into the nasal cavity about eight inches by one. An examination revealed the fact that the superior or ethmoid turbinated bone was necrosed, and as much as possible was removed below this. In the middle meatus were five polypi which seemed to hang in folds of mucous membrane and arranged one above the other. They varied in size from that of a duck egg to the egg of a bantam. The whole came away together, and seemed to be in the mucous membrane covering the superior turbinated bone. The curette was freely used, and all necrosed bone removed as far as possible. The wound was washed out with cold water and afterwards with weak chinosol solution, and the cavity was plugged with absorbent cotton wool. The hemorrhage was excessive. The operation was performed in the Travis, the horse standing well. The following day the patient was doing well, was comfortable and taking food, but the dressing was not disturbed. The next day the dressing was removed and was very offensive. More necrosed bone was removed by the curette, part of the ethmoid cells being included, and some of the maxillary or inferior turbinated bone. The cavity was well syringed out with a weak solution of carbolic. The discharge remained very offensive and copious for a week. The cavity was examined daily, and all necrotic pieces removed. The wound was washed out three times daily by using an enema pump with weak solution of Chinosol, Pot. permanganate, Carbolic acid, cold water, etc. Mineral and vegetable tonics with arsenic were given. The discharge was so offensive that his attendant, who is used to such things, asked me to have him destroyed, but it gradually decreased both in amount and effluvia. The horse then began to put on flesh, and resumed work on May 8th, and has been at work ever since. I saw him about a month ago, and the only evidence of an operation is a slight scar about four inches long and a slight indentation. He is doing fast work, and makes no noise. He was a good patient and never any trouble to dress.

AMPUTATION OF THE PENIS.

The subject in this case was a brown Shire gelding, about 12 years old, and it was suffering from paralysis of the penis. After the usual treatment had been tried without result, it was decided to amputate. The animal was chloroformed after being cast on the off-side, the near hind leg drawn well forward and secured to the fore leg. The whole region was well washed with hot water

and soap, dried and thoroughly disinfected. Owing to the swelling and ulceration it was necessary to amputate high up, and we divided the frenum which joins the prepuce to the penis on its dorsal surface. After taking up the vessels with the forceps, the catheter was passed and ligatures applied above and below the seat of operation. By dissection the urethra was exposed for about two inches and a longitudinal incision made on the catheter, which was then withdrawn and the free edges of the urethra were sutured to the surrounding tissues in the form of a triangle the base, of course, being towards the free end of the penis, the urethra having been previously divided transversely. The ecraseur was put in position, but before the whole organ was divided the chain broke. A ligature was put on and the operation finished with the knife, when it was found that the corpora cavernosa had been entirely divided by the ecraseur and only the tunica albuginea by the knife. The hemorrhage was slight, and subsided almost immediately the patient got up; he was placed in a stall and the usual instructions given as to feeding. About three hours afterwards the horse staled and hemorrhage began, and he was still bleeding when I saw him an hour afterwards, but nothing to be alarmed at. As night was approaching, I cast him again and found the bleeding was from the vessels of the prepuce. The wound was plugged and a suture inserted drawing the prepuce together. This was removed the following morning, the ligature from the penis coming away in about 10 days. The after treatment consisted of cold water from a hose pipe twice daily; mag. sulph.; pot. nit. The animal never experienced any difficulty in urinating, and never missed a meal. The operation was performed on Friday, September 22 and the animal was certified ready for work on October 28, exactly five weeks later, during which time there was a decided improvement in condition.

LIGHTNING?

The animal concerned in this case was an aged hunter mare which had been pensioned off for about three years, during which time she had been out at grass. I found her standing in a paddock in a comatose condition, head hanging down and much swollen, blood vessels full of blood, the conjunctival mucous membrane was protruding above eyelids, constant shifting of limbs, with twitching of quarters, and attempted to eat at intervals; pulse, 60, full and slow, temperature, 101.2, respiration, 12, shallow. On the near side of the crest, midway between poll and withers, was a hairless spot not more than a quarter of an inch across, which was dry and purple in colour, and looked like one of those abscesses met with on the neck in horses, which had healed, and to which I did not pay much attention. It was impossible to move the mare except by main force.

Diagnosis: Venous congestion of the brain. *Etiology:* Doubtful.

Prognosis: Guarded, probability of recovery dependent on cause. I proposed to treat the symptoms and see again next day, but the owner thinking she was in pain wished her to be destroyed, and this was done.

The post mortem showed rigor mortis to be almost entirely absent; subcutaneous vessels full of blood, slight extravasation below serous membrane of large bowels and stomach, small fatty tumour hanging in folds of peritoneum from the region of kidneys; when liver cut into, blood ran into cut dark in colour. Old pleural lesions. Heart contained dark fluid blood and showed extravasation under the epicardium. The tissues immediately below the purple hairless patch were discoloured and there was laceration of the muscles, which were dark coloured, in a downward direction for about four inches, when there was a sharp turn in the direction of the shoulder, the laceration terminating immediately in front of the scapula.

My reason in reporting this case is that in my experience

it is unique, and the fact that the post mortem of cases of lightning are often very unsatisfactory. I have often wondered whether chemical analysis of the blood would reveal anything.

STRANGLES.

A chestnut filly hackney, three years old, was broken in as a two-year-old and turned out for the winter, and was not noticed to be other than all right and doing well until April 20th last, when the owner received the news that she did not seem well, and I was asked to look at her. I found her standing with nose poked out, anxious expression, pulse accelerated only slightly, and quick in character. A manipulation of the throat and poll revealed nothing, and the temperature was 100.5. On being led out of the stable she moved stiffly, with her tail raised and quivering, and when turned round moved all in a lump and seemed excited. There was no evidence of injury. My diagnosis was doubtful—possibly tetanus, or poll evil, or injury. I treated her with salines, put her in a quiet box, and ordered soft food. She continued in this condition for about a month, during which time she was seen by a professional friend, but we got no further. She ate fairly well, but drank very little, and often stood with her teeth resting on the manger. About this time I noticed, or fancied I did, a slight swelling and tenderness under the wing of the atlas on the near side. This was blistered, and she seemed to improve for a week or so. By this time, of course, the tetanus and poll evil theory had been exploded, and I still thought it possible there might be some injury to the atlas. The enlargement did not increase, and the use of the exploring needle did not yield any result, so I advised that she be turned out and we would wait for something to turn up. I saw her continually for some weeks without any alteration taking place. She grazed well and galloped about, but carried her head almost parallel with the ground, and when caught the least pressure on the nose would cause her to run back. She was losing flesh, but feeding beasts in the same field were making no headway.

On the 19th of August I noticed three or four large diffuse swellings underneath the mane and extending from the centre of the crest to the withers, another on the near thigh, on the inferior border of the neck, and there were several small, round, and hard bodies which were painless. These disappeared and re-appeared several times, and on examining her on September 22nd I found to my surprise several small spherical nodules, hard and apparently painless, along the crest, which made me think of sarcoma. About ten days later I went prepared to dissect out one of these nodules, if still present, and to my further surprise found three of them fluctuating. I opened two of them at once, and their contents were typical of strangles pus. Although I have not had it examined under the microscope, I have no doubt the cause of the whole trouble has been the streptococcus of strangles. There were a dozen abscesses in various stages, and up to the present time I have opened about twenty. She is having tonics, mineral and vegetable, with arsenic, and one injection of nuclein. Her head is much freer, she drinks plenty of water, and is much improved in condition. There are still a few more abscesses to discharge their contents, but she is getting so lively that they will probably have to take their course. I anticipate she will make a complete recovery.

TWO REMARKABLE RECOVERIES.

Mr. OVER. The first case was one of prolonged paralysis in an Alderney cow after milk fever. She went down on April 14th last, but got up the same night after oxygen treatment. Five days later she went down again and was very ill. She had several injections be-

tween that day and April 22nd, when she seemed quite herself, feeding well and milking well, but had practically no power in the hind limbs. Nux vomica and ammonia were given three times daily, and the legs rubbed and the back stimulated. At the end of a fortnight the owner was advised that she had better be killed, but he would not consent. She was on a good bed in a box, and would scramble round, but could not use her legs. On three different occasions she was pulled up in slings, but lowered again. She remained in the same condition till September 24th, when, the door having been left open, she got up and walked out. She had been down for twenty-two weeks and four days in all. She has been able to get up and down freely ever since, but rolled a little in her walk. There were no sores on her.

Case II.—A big blood hunter in what appeared to be a perfectly hopeless case of internal hæmorrhage. The animal was of very nice quality, five years old, and measuring 16.3 hands. Mr. Over was called in on May 30th last, and the history of the case, as given to him, was that the horse was turned out into a field with some polo ponies on the previous day, and in the morning it was found down and unable to rise. A passer-by stated that he had seen one of the ponies kicking at it. There was a contused wound on the top of the croup, and it was afterwards found that the last rib but three on the near side was broken about half-way up, though there was no mark on the skin at that point. The kicking did not appear to have been very much. The horse was lying on its off side, and was breathing very jerkily, and opening and shutting its mouth spasmodically. The visible mucous membrane of the eye, nose, and mouth were white, and the pulse was quite imperceptible. The animal made attempts to get up on its forelegs, but never succeeded in getting even its chest off the ground. It lay back absolutely exhausted, and he (Mr. Over) told the owner that it was a case of severe internal hæmorrhage, and that he did not think that anything could be done to save it. A hypodermic injection was given, and an hour afterwards an attempt was made to administer a drench of whisky and Ammonia, Nux vomica, and Digitalis, but very little could be got down, as the animal practically fainted and was unable to swallow. He then had it rugged up well, bandaged, etc., and went away. Returning two hours later with some adrenalin he found the condition of the patient to be just a little more hopeful. The pulse was still quite imperceptible, but the buccal membrane had a faint pink tinge round the borders of the teeth. He gave another injection of ether and one of adrenalin mixed with some normal salt solution. He called about two and a half hours later expecting to find the animal dead, but it was then up, and although very unsteady was walked about sixty yards with a man on either side into a big loose box. It had another injection of adrenalin, and stimulants consisting of ammonia, nux vomica, and digitalis. The injection of adrenalin was repeated twice next day, and once the day after that; the further treatment consisting of the stimulants already mentioned and careful nursing. The animal gradually improved, and was on a fair way to recovery on June 10th, when he ceased to visit it. One or two abscesses formed in the neck, probably from the injection of ether. An extraordinary circumstance was that he lost sight of the horse, as it left the neighbourhood, but about a month ago he was sent for to see it at a place about a hundred miles off, though he did not know when he was called that it was the same horse he was going to attend. Its heart was not then quite right, and there was a little intermittence in the pulse, but there was nothing else the matter, and it had been doing a little work. When seen again about a fortnight later it was fifty per cent. better.

Mr. REYNOLDS described the first case mentioned by Mr. Over as a very peculiar one. It was usual when a

cow went down and some attempt was not made to get it up, or if it was got up and it did not stand, to find both hind legs swollen, degeneration and abscesses; and the animal generally died from septic trouble in a fortnight or three weeks afterwards.

Mr. GOLD asked whether Mr. Over attributed the good results in the second case to the adrenalin?

Mr. BROOKE: Was any definite conclusion formed as to the seat of the hæmorrhage?

The HON. SEC.: How did Mr. Over know there was hæmorrhage?

Mr. PARKS: What was the bedding in the cow's box?

Mr. OVER, replying to these questions, explained that the cow was in a hovel and there was plenty of clean straw for bedding, which would largely account for the absence of bruises. He agreed with Mr. Reynolds that in most cases of this kind there was degeneration, but it did not occur in the one under notice.

As to the hæmorrhage in the hunter, he thought at the time that there was a rupture of the liver and that the capsule had given way. He did not know where the blood went, but it all disappeared. He was afraid the hæmorrhage might break out again. He had galloped the horse well twice since, and he believed that the difficulty was all over, and that if the horse was placed before a dozen veterinary surgeons to examine they would pass it as sound if they did not examine its heart. Mr. Over added, in answer to Mr. Gold, that the pulse was still intermittent after galloping, but nothing like so noticeable as before.

Mr. BROOKE: Why should it be intermittent after hæmorrhage?

Mr. OVER said that he could not understand. The horse got better when given the adrenalin and that was all he could say. It was injected twice on the first day, twice again on the following day (May 31) and once the day after (June 1), and once again the next day (June 2). He considered either to be a very good thing in these cases. He could only remember one similar recovery in a case in which it was practically certain there was internal hæmorrhage, and in that instance the animal went perfectly blind.

"DOPING" RACE HORSES.

Mr. PARR spoke on the duties of an honorary veterinary surgeon at race meetings. He officiated in that capacity at Leicester races, and on two occasions had been asked by the stewards to examine a horse which they thought had been doped. He refused, and now he wanted to know what other practitioners would have done. He was asked if he could tell whether a certain horse had been doped, and he replied that he could not. A younger man might have been led to examine the horse and give an opinion, but unless he knew more than he (Mr. Parr) about doping it might have led to serious consequences.

CERTIFICATES ON DEATHS FROM LIGHTNING.

Another matter which he desired to mention was the giving of certificates in cases in which horses were believed to have been struck by lightning. On one occasion he was asked to examine a horse worth £200 and insured for £100, which was said to have been struck. It was paralysed, but he could see nothing upon which to base the opinion that it had been struck, and he came to the conclusion that, frightened by lightning it had run against a tree and so caused some fracture of the vertebræ. As a matter of fact such a fracture was found after death. There was no external burns, nothing except the paralysis, which they did get from lightning. What ought one to do in such a case in order to be fair both to one's client and the insurance company?

CERTIFICATES ON "TRIMMED" DOGS AT SHOWS.

Again, when officiating at a dog show, he was asked

for a certificate that a certain dog had been trimmed. He declined as it was not a veterinary point at all, but one which it was the judge's duty to decide.

THE TITLE OF "PROFESSOR."

Mr. PARR was strongly of opinion that no man ought to call himself "Professor" when he was only in ordinary practice. A professor was a man occupying a chair of teaching at a college or school, and when he left that college or school he ought to drop the title. It was as great a form of advertising as if a man advertised that his colic drinks were the best. There were a number of men who had left off teaching and who, in his opinion, were trading on the title of "Professor."

The HON. SEC., alluding to the lightning case quoted by Mr. Parr, suggested that the vertebræ might have been broken by the animal falling after being struck by lightning.

Mr. PARR agreed, but said the point was whether the practitioner called in should give a certificate that the horse had been struck by lightning.

Mr. REYNOLDS stated that after a heavy thunderstorm in his neighbourhood he was called to see several animals and found distinct evidence of lightning. The farmer explained that three cart horses which were under a tree fell down and were supposed to have been struck. While two got up apparently uninjured, the third showed every symptom of partial paralysis of both hind legs, but there was no singeing of the hair. Some one afterwards gave a certificate that it was probably caused by lightning, but there was no sign of injury.

Mr. BAINBRIDGE said that in a case which had come under his notice some sheep sheltering under a hedge were supposed to have been struck by lightning, but there was not a single mark of singeing. That they were all killed by lightning was evident when the carcasses were skinned.

Mr. PARKS pointed out that if there was any doubt in such cases most insurance companies were satisfied if the veterinary surgeon stated that the symptoms were consistent with what he would expect if the animal had been struck by lightning.

With regard to the use of the title "Professor" he thought it was applied generally as an act of courtesy.

Mr. TAYLOR replying to Mr. Parr's question as to the duties of a veterinary surgeon at a dog show, mentioned that it was laid down in the Kennel Club rules that if a dog had been cropped or docked, or if there was any deviation from the normal, it was for the veterinary surgeon to certify, should the judge call upon him to do so.

SAND IN THE INTESTINES.

The PRESIDENT said he had had a number of gripe cases during the past few weeks. On two farms on the same estate with a very sandy soil, seven and five horses respectively were affected. The seven all got well, but two of the five were very ill indeed for a time, though they eventually recovered. When their bowels became open he was surprised at the appearance of the dung, and found it was nothing but clear sand. They dunged nothing but sand for two days. Two years ago a horse at the same farm was taken ill and died, and at the post mortem two buckets full of sand was found in it. The only explanation he could suggest was that the grass was very short owing to the dryness of the season, and in nibbling at it the horses took up the sand. There was also a low pool on the farm with a sandy bottom and when the animals went to this to drink they pounded the water and probably drank sand in with it. Two seasons ago, however, the grass was not short. Another farm four or five miles away was very sandy, and there a horse had died in the same way.

Mr. TAYLOR stated that in camp on the Devonshire

Downs during the summer, the horses nibbled in the lines and took up a lot of sand. The stomach of one which died, when a post mortem was made, was found to be half full of sand.

This concluded the afternoon's discussion, and in proposing a vote of thanks to the members who had contributed essays and specimens, the Hon. Secretary said he thought a meeting of that description once a year would prove extremely interesting and useful.

On the question of treatment of acorn poisoning, he suggested that the two members who had dealt with the trouble extensively should collaborate in producing a paper setting forth a successful treatment.

Mr. BURCHNALL seconded, and the motion was carried unanimously.

H. J. DAWES, F.R.C.V.S., Hon. Sec.

NORTH OF IRELAND VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held in the Clarence Hotel, Ballymena, Co. Antrim, on Thursday evening the 16th November, at 5 o'clock p.m. In the unavoidable absence of the President, F. W. Emery, F.R.C.V.S., the chair was occupied by the Vice-President, Howard McConnell, M.R.C.V.S.

The following members were present: Messrs. Robert Kernohan and John Kernohan, Ballymena; J. A. Thompson, J.P. Lurgan; J. J. Ross and J. A. Jordan, Belfast; John Gault, Ballymoney; Gordon Stewart, Ballymena.

Apologies were received from Messrs. J. Ewing Johnstone and W. C. M. Smith.

The minutes of the previous meeting having been read and confirmed were signed.

The SECRETARY read a communication from Mr. A. M. Creighton, Lisburn, resigning his membership of the Association, and it was unanimously decided to request Mr. Creighton to reconsider his decision.

A letter was read from the Editor of *The Veterinary News* (H. A. Woodruff, M.R.C.V.S.) re the fund for assisting Mr. Kirk in the appeal raised by the L.C.C. to compel veterinary surgeons to pay tax for the use of the College crest: and requesting financial support either from the Association or from both it and individual members.

It having been pointed out by the Treasurer, that of late a great many demands had been made on the funds of the Association, and that in future we would require to exercise a little more economy, it was resolved that the Secretary be requested to write and express regret that as an Association we cannot see our way to subscribe, but that we wish every success to the effort.

A letter was read from the Secretary of the Royal Sanitary Institute intimating that the next Congress of that Institute would be held in York next year, and inviting this Association to appoint delegates. No action was taken in the matter.

Messrs. Thompson and Jordan verbally submitted their report in connection with the Public Health Congress, held in Dublin: it was considered satisfactory, and was passed.

AFFILIATION WITH N.V.A.

An interesting discussion took place as to the position this Association was going to take with reference to the amalgamation scheme. Mr. Thompson, having spoken at considerable length, and having thoroughly considered the question in all its bearings, proposed the following resolution, which was seconded by Mr. Robert Kernohan, J.P.: "That the Association adopt the amended

rules and take the necessary steps to affiliate". This was passed unanimously.

At this stage the Secretary read the following communication which he had received from the President (F. W. Emery, F.R.C.V.S.) who had kindly consented to read a paper:

"Dear Mr. Jordan,—I shall be unable to attend the meeting at Ballymena to-morrow, as I have to go home this evening owing to the very serious state of my father's health. I am forwarding you the paper I prepared, it is in the rough, and owing to the adverse circumstances under which it was written I am afraid it is of little merit."

The SECRETARY was requested to write expressing sincere regret at the sad circumstances under which the President was prevented from being present.

At the request of those present Mr. Jordan read the paper prepared by Mr. Emery.

THE RELATION OF VETERINARY SCIENCE TO PUBLIC HEALTH AND AGRICULTURE.

By Mr. F. W. EMERY, F.R.C.V.S.

The application of every branch of veterinary science has a very decided bearing on the well-being of the community. In conserving life and promoting animal health; in improving the general standard of our animal population, in preventing their undue abuse in transit; in eradicating infectious and contagious disease; and finally, in bringing our knowledge of comparative pathology into use in connection with meat inspection, we are constantly working for the material prosperity of the nation and at the same time protecting and safeguarding the health of mankind.

I am sure we are all familiar with instances in which, by the ability and industry of the members of one or more generations of a family, great wealth has been amassed: but owing to all concentration and thought having been devoted to this one object the health of the workers and their dependents have been ignored, with the result that ill-health and disease have been allowed to gain such footholds as to be ineradicable, and, all too late, it has been recognised that power and wealth are but poor substitutes for that greatest of all blessings—health. That which is true of the individual family may also be true of a nation, taken as a whole, and if we give the matter a little consideration, I think it will be brought home to us that in our own country this striving after material prosperity has taken too great a hold of all. If we take an intelligent interest in the happenings taking place around us, or if we even take but a cursory glance at our daily papers, we cannot fail to observe that those who are combined to form Governments, and those who are combined in opposition to those Governments, are all combined in endeavouring to persuade the public that on the adoption of their particular ideas the material prosperity of the nations depend. We seldom, if ever, see any of our great leaders devote a few minutes to telling their admirers that wealth without health is a delusion and a snare, and that in the building and maintaining of a nation it is absolutely essential to make and enforce provisions for the prevention of disease and for the propagation of a vigorous healthy race. If these essentials are attained, wealth and prosperity must follow as surely as day follows night.

There can be no two opinions as to the necessity for the creation of a State Department of Public Health. If we had a Minister of Public Health upon whose shoulders would rest the responsibility for the workings of the Public Health Service, great and good results would be quickly manifest.

The veterinary profession has already rendered inestimable services to the cause of public health, and I am

confident our profession is destined to play a great part in the future in protecting the community from preventable disease, more especially in so far as those diseases are concerned that are intercommunicable to man and beast.

The present day veterinarian, owing to his unique and and thorough knowledge of our domesticated animals, both in health and disease, by his close observation and clear understanding of the various phases of the many infectious diseases from which they suffer, and as a result of the very efficient manner in which he has been grounded in anatomy, histology, physiology, pathology, and bacteriology, is in a position to offer invaluable advice to those charged with public health administration. Moreover, he is the only professional man in the British Isles who is entirely competent to discharge the onerous and important duties of meat inspection and dairy herd examination. Efficiency in these departments can only be secured by placing them under the direction and control of a veterinary service of health. In my opinion the time has more than arrived for the establishment of such a service, and the following quotation from a recent speech of Sir William Turner, K.C.B., the very distinguished principal of that great seat of learning, Edinburgh University, is ample proof of the correctness of that view. He says: "It is clear that the veterinary profession is now called upon to take a wide grasp of questions affecting the public health—the health of man as well as of animals. You cannot, indeed dissociate the public health of man from the public health of the animal, because there are so many infectious diseases that the animal can and does transmit to man, so that human medicine and veterinary medicine have a very close alliance and association with each other. Therefore we must now look at the veterinary profession as a profession which is not only concerned in, if I may say so, the doctoring of animals, but which has to do with disease of various kinds in its wider aspect, embracing man and animals."

Efficiency and economy are co-efficients, and in order to secure the very best results in meat and dairy inspection, you must apply similar regulations to the country as a whole. You must establish an uniform service with uniform administration enforcing uniform action; to this end, regulations providing for a certain amount of individual discretion should be drafted for general guidance. In support of the adoption of an uniform system of meat inspection I cannot do better than quote from the report of the Royal Commission on Tuberculosis (1898).

"The evils arising from this want of uniformity are manifold. Very strong representations were laid before us on the part of the butchers and meat traders, and also on behalf of agriculturists who supply the butcher, as to the effect of this want of uniformity upon their business. It is obvious, we think, that these complaints are well founded. Producers and traders are making no unreasonable demand when they ask that a recognised standard should be observed, and that meat which after inspection is pronounced fit for sale in one market should not be liable to seizure in another, because the inspecting authority happens to differ in opinion as to the extent to which tuberculosis may be dangerous."

A very able article on meat inspection which appeared in the January number *Journal of Meat and Milk Hygiene*, concludes with the following suggestion:—"The central authorities must exercise a controlling influence over the work of local inspectors, and that can only be done by the appointment of a veterinary surgeon as the supervising officer, who prior to his appointment must have had practical experience in the work of meat inspection." The adoption of that recommendation would go a long way towards securing that uniformity which is not only desirable but absolutely necessary.

MEAT INSPECTION.

Dealing with meat inspection, I suggest that meat stamping is an essential: I also suggest that meat should be graded into three classes and marked accordingly.

First Class.—Should include all meats found absolutely free from disease, and in connection with which every reasonable precaution has been taken to prevent surface or other contamination.

Second Class.—All meats of inferior quality and of less nutritive value than those in Class I, but which have been found free from disease.

Third Class.—All meats some portions of which have been found to present evidence of disease, but from which it is believed all elements of danger have been removed by the extirpation of the affected tissues.

It will be observed that I do not suggest the use of the carcasses of diseased animals in cases in which it may be found injudicious to attempt the separation of disease lesions from healthy structures. In many Continental cities such carcasses are subjected to a special process by which all noxious organisms are rendered inert. Such meat is sold at a very low figure, and can be obtained only at places specially set apart for its sale. By this means it is claimed that a meat having a certain amount of value as a food is made available for the very poor, such as, unfortunately, are to be found in all large towns. Apart from the revolting idea of feeding our people upon the products of disease, the appearance of the sterilized meat is far from enticing.

I would be very sorry to see any attempt made to apply such a custom to Great Britain and Ireland, which can boast of such enormous wealth. It would be far better to lay claim to some of this wealth for use in bringing a pure food to our markets to be sold at a price within the reach of all. At the present time a large quantity of good palatable food is destroyed simply because it has not been sold at a set figure placed upon it by a trade. I think such methods ought to be made illegal, and places should be provided in all large towns where such commodities could be offered and sold at whatever prices the poor may be able to afford.

The slaughter of all animals intended for the food of man should be carried out under the highest sanitary conditions. Absolute cleanliness of the persons employed, and the instruments used should be enforced. If a knife has been used for cutting into morbid tissues it must not be used on healthy structures until it has been thoroughly sterilized, otherwise sound meat may become contaminated. All carcasses should be subjected to examination as soon as possible after the animals are slaughtered, and those revealing no abnormal condition at once passed on to the cooling house; those manifesting conditions rendering the whole body unfit for human food should be moved forthwith to the destructor; any body not placed in either category to be labelled for detention and further inspection and sent into a special cooling compartment. In addition to this procedure, I hold that all uncondemned carcasses should be again inspected after "setting" and prior to removal from the slaughter-house.

After leaving the abattoir it is absolutely essential that the greatest care should be exercised in avoiding surface contamination. Thoroughly cleansed covered vehicles must be used in its conveyance to the retailer's premises which must also be arranged on up-to-date and sanitary principles. It will also be obvious that no unhealthy or diseased person should be permitted to handle meat or serve in any capacity in a butcher's establishment. If these latter precautions are not taken, the great care exercised by breeders and rearers in the production of healthy stock, and by the public health authorities in providing for efficient inspection, will be rendered nugatory.

As an example of want of care in avoiding surface

contaminations I would direct your attention to the pork trade of the North of Ireland, carried on, as it is, under most undesirable conditions. Pigs are slaughtered at the homesteads and their carcasses hung for "setting" purposes in a byre or outhouse, they are subsequently conveyed to market in ordinary farm carts, and the market place is often situated in the open street. If purchased for railway transit the railway trucks used may have been previously employed for any other purpose and need not have been subsequently cleansed or disinfected. In cities ordinary lorries are used, and in sea transit the bodies are stowed on the open deck exposed to all sorts of contamination. During the whole procedure the carcasses remain uncovered, and no thought is given to cleanliness.

In the actual work of meat inspection, I suggest that when any abnormal condition observed is proved to be due to any of the following causes, the whole carcass should be condemned: Malignant tumours (sarcomata, carcinomata, lymphadenoma), septicæmia, pyæmia, black quarter, anthrax, louping-ill, tetanus, erysipelas, pneumonia, pneumo-enteritis, croup, diphtheria, the various contagious and infectious diseases; generalized tuberculosis (indicated by milary tuberculosis of the lungs), general tuberculosis, probably the result of extension through the lymphatic system, tuberculosis of two or more important organs, and tuberculosis of deep-seated glandular structures; trichinosis, some cystic worms (*Cirrus cerebralis*, *Cysticercus cellulosus*, *Echinococcus veterinorum*, *Cysticercus bovis*, etc.); *Coccidiosis* (liver and intestines of rabbit); carcasses of animals that have died from any cause whatever, of course including accidents of parturition; newly-born calves; and all very old emaciated animals, the flesh of which can have no nutrient value—this especially applies to old worn out boars and bulls.

The conditions admitting the passing of portions of a carcass only must, to a great extent, be left in the hands of the professional officer, who will be in a position to accurately and scientifically weigh the evidence manifested by the appearance, extent and nature of the pathological lesions presented—lesions, the result of external violence, benign tumours, glandular tuberculosis with lesions indicating that they are primary and have not extended, and some forms of actinomycosis are amongst the conditions which most inspectors would feel justified in so classifying. At the same time I do not think it would be acting in perfectly good faith with the community to allow any carcass to be marketed as "first-class" if any portion of it has had to be extirpated. It should be remembered also that while cooking may destroy living germs, the process is not always efficient in minimising the effect of toxins.

INSPECTION OF DAIRIES.

The Dairies and Cowsheds Order has opened up another field in connection with public health work in which the veterinary surgeon's services are essential if efficiency is to be attained; but here, again, uniformity of action is needed, and, in view of the fact that milk is frequently produced at places far distant from where it is consumed, and that there are very grave objections to granting the right of entry to one local authority into dairies situated in the district of another authority, it seems to me to be imperative that a legislative measure should be passed having universal application and compelling uniformity of administration.

The report of the last Commission on Tuberculosis affords ample proof of the absolute necessity for such legislation, as the following extracts will show:—

"There can be no doubt that a considerable proportion of the tuberculosis affecting children is of bovine origin, more particularly that which affects primarily the abdominal organs and the cervical glands; and further, there can

be no doubt that primary abdominal tuberculosis, as well as tuberculosis of the cervical glands, is commonly due to ingestion of tuberculous infective material."

"The evidence which we have accumulated goes to demonstrate that a considerable amount of the tuberculosis of childhood is to be ascribed to infection with bacilli of the bovine type, transmitted to children in meals consisting largely of the milk of the cow."

"But it must be remembered that we have found cases of tuberculosis in adult man sufficiently extensive to incapacitate the patient from the ordinary duties of life, and in two instances ending fatally, in which we were able to attribute the disease solely to the effect of the bovine bacillus."

The work of the veterinarian under this Order is more particularly directed towards the byres and the general condition and health of the cows. There is little or no difficulty in advising as to new structures, but unfortunately we are not likely to be often consulted in this respect. Our more frequent duty will be to offer suggestions as to the best methods of altering existing buildings, so as to bring them as nearly as possible into conformity with up-to-date principles and ideas. As a brief outline, I would suggest that all floors and walls should be rendered impermeable, that the surface of both should be of such a nature as will admit of thorough cleansing, that all inside drainage should be surface, with channels leading to traps situated outside the sheds. Manure pits should be situated at a sufficient distance from byres as to prevent air contamination; they should be impermeable to moisture, away from houses, wells, or water supplies. As much cubic space as possible should be allowed for each animal; this is very important, because the greater the cubic space the less often will it be necessary to flush the compartment with pure air, and consequently a more equable temperature can be maintained. Adequate arrangements must be made for the ingress of pure and the egress of impure air.

INSPECTION OF COWS.

Probably the periodic examination of the milk producer will be considered our more important duty, and I need hardly say that it behoves us to put forth our best endeavours to secure the best results. Every animal kept in a dairy should be in a state of perfect health, and should any deviation from that state be observed, the ailing beast should be removed and isolated forthwith. The period of isolation must depend upon the cause, but in any case the segregated animal should not be again brought into contact with others until the veterinary inspector issues a health certificate for it. The milk of isolated animals should not be used for human consumption, nor for any other purpose, unless it has been sterilized by boiling or otherwise. That the boiling of milk does not remove all source of danger is clearly shown by the following extract from a very able article in *The Hospital* by Dr. H. J. Hutchens:—

"Poisoning by bacilli of the enteritides group generally takes the form of septicæmia. The bacilli can be recovered from the blood during life and from the spleen after death. But organisms of this group give rise to a highly thermostable toxin which will resist boiling for some little time. This is a matter of considerable practical importance, because it can be readily understood that these organisms might be present in milk, for instance, in which they would multiply and produce their toxins. If milk were heated before being used as food the bacilli might be destroyed while the toxins remained, and these latter might then give rise to acute symptoms of gastro-enteritis in those who consumed it."

And now, in concluding this portion of my address, and in support of my contention that a much more rigorous system of inspection than now exists should be

inaugurated without delay, permit me to again quote from the Royal Commission on Tuberculosis:—

"In the interests, therefore, of infants and children, the members of the population whom we have proved to be especially endangered, and for the reasonable safeguarding of the public health generally, we would urge that the existing regulations and supervision of milk productions and meat preparations be not relaxed, but on the contrary the Government should cause to be enforced throughout the kingdom food regulations planned to afford better security against infection of human life through the medium of articles of diet derived from tuberculous animals."

Agriculture and the art and science of veterinary surgery and medicine stand in very intimate and practical relationship. It would be a rather difficult task to form anything like an accurate estimate of the value rendered to the "world's oldest profession" by members of our calling, because, in so far as the work of the general practitioner is concerned, we have no available data to go upon; but unquestionably the benefits conferred have been enormous, and if they could be translated into a monetary equivalent the total would reach a very large amount. But, apart altogether from this aspect of the matter, we have more than established our claims and rights to the utmost consideration, from the great fact that much pain and suffering have been saved our domesticated animals by the application of our skill and knowledge in the treatment of their injuries and diseases.

The following extract from the writings of a distinguished agriculturist of fifty years ago speaks for itself, and may with equal relevance be applied to our own time:—

"Associations have been formed and colleges founded for the advancement of veterinary science, and eminent practical professors are engaged in the dissemination of its principles, so that it has now taken a very elevated position. Its practice is no longer left in the hands of the uneducated and unskilful; the horse, the dog, and beasts of the farm generally are no longer subjected to the tortures of callous-hearted and presumptuous ignorance, but are placed under the care of gentlemen who have gained the general respect of the community and the confidence of those with whom they come in immediate contact, and whose experience, intelligence, and humanity entitles them to the onerous position their profession calls upon them to fill."

It may not be uninteresting to you if I quote examples of treatment adopted in the latter part of the seventeenth and early part of the eighteenth centuries. For instance, for animals suffering from farcy, medicine was ordered to be administered to the ears of the horse and drawn up therein, and for certain lamenesses it was advised that a turf should be cut and secreted, and in proportion as the turf decays and wastes away so shall the lameness of the horse gradually depart. These quotations clearly show the vast amount of suffering to which animals were subjected owing to the crass stupidity and ignorance of those into whose care they were entrusted; they also afford a means of estimating the great boon conferred upon animals by the establishment of our profession.

In the early part of the eighteenth century many medical men began to take an interest in veterinary medicine, and works on farriery of that period show a distinct advance, and were mostly modelled on Continental systems and teachings. During this period veterinary literature was fairly abundant in France, Germany, and Italy, but comparatively few works were translated and made available in these countries. The establishment of the London Veterinary College in 1792 may be taken as the actual birth of our profession in so far as these islands are concerned, and although in its earlier days the College experienced many vicissitudes it gradually

worked its way into public esteem. Now, looking back on this long vista of years, I think the veterinary profession has every reason to be proud of its achievements, for though, but limited in number and not overburdened with wealth, our progress has been phenomenal. We may have been equalled by others, we certainly have not been excelled.

In connection with the prevention, control, and eradication of infectious and contagious diseases, it would be quite possible to afford an approximate estimate of the actual monetary value rendered to the state owing to the preserving and safeguarding of animal life, and the prevention of dislocation in the various trades which are dependent on animals and animal products, and while it is not my present intention to offer you the result of my many computations, I can say, without the slightest fear of contradiction, that veterinary science has conferred and is conferring inestimable benefits on the community. The present generations have little knowledge of the terrible ravages caused in these countries by the prevalence of animal diseases, and so they are apt to overlook the necessity for preventive measures, but it should never be forgotten that our flocks and herds have been decimated on more than one occasion by the introduction of infection, and it is a matter for the sincerest congratulations that the following diseases have been stamped out of Ireland: Cattle plague (1877), Foot and mouth disease, Pleuro-pneumonia, Rabies, Glanders, and Epizootic lymphangitis, and White swine fever. Anthrax and Sheep scab still remain; they are probably under more direct control; they provide many knotty problems for solution which I have no doubt will be answered satisfactorily. By continued study and investigation we may practically rest assured of ultimate success.

There are a number of diseases that might be scheduled under the Contagious Diseases (Animals) Acts with advantage. I think we are all agreed as to the inclusion of contagious abortion and tuberculosis. Of the former, I do not think it is by any means so widespread in Ireland as some would have us believe. Still, it is by no means a negligible quantity, and, as individual effort is quite insufficient to cope with its ravages and reduce the loss which it occasions, a united effort is called for. No apology need be made for insisting on the State control of tuberculosis. Public Health authorities have shown it to be a source of great danger to mankind, and that it is the cause of considerable loss to the agriculturist is admitted. Why, therefore, do we not take some practical steps to limit and remove the danger, and also put a stay upon the drain of national wealth caused by its widespread existence? Our present apathy in this respect is most extraordinary and almost criminal.

As members of the veterinary profession, I think it is our obvious duty to press this matter; we should lose no opportunity of explaining to those with whom we come in contact the nature of and dangers associated with this affection, and also that with perseverance, rigidly following a certain code, and by the aid of tuberculin, it is quite possible to stamp it out. It cannot be too strongly impressed upon stock owners that the focus of infection is, as a rule, an infected animal, and that unless the causal organism is present, other conditions—such as in and in breeding, insufficient food, excessive milk production, darkness, dirt and other adverse circumstances—cannot give rise to the disease; nor can cleanliness, fresh air, light, and exercise entirely prevent animals from contracting it if they are exposed to infection.

In order to successfully compete with his foreign rivals the British farmer must keep abreast of the times; with him, as with all others, education is the keynote of success. Can we render assistance? I think so. Some time ago veterinary lectures for farmers were inaugurated, and had they been conducted on right lines much

benefit might have been conferred; but I understand that these addresses usually resolved themselves into discussions on diseases and their treatment, prescriptions being asked for and given. I think evil rather than good would follow such procedure, because, as every professional man must know, it is only possible to indicate a proper line of treatment after close observation and an exhaustive examination of the patient. From these the trained clinician must make many deductions before he can suggest a course of treatment, or give a prescription, likely to be beneficial.

In lecturing to laymen the veterinarian should first address himself to sanitation and hygiene, and going further afield he might give his audience sound information on the best means of exterminating such pests as the warble, sheep scab, and redwater. It would be useful and interesting to explain how sheep dipping may be utilised to aid in the eradication of redwater in cattle. Farmers should be told of the means adopted in other countries in these connections, and the enormous saving that would accrue to our country should success be attained.

Then the important question of how to improve the breeds of our flocks and herds affords great scope for the instillation of new ideas and methods in our lectures. The improvement of our dairy herds is a crying necessity, and our farmers must exert themselves if they are to advance or even retain their position in the butter markets.

It is essential that our dairy owners should keep accurate records of the quantity of milk yielded by each cow; by this means unprofitable animals could be detected and at once disposed of. The Danes discard, for milking purposes, any cow not yielding over 600 gallons per annum. The cows with a higher yield are used for breeding, and by a gradual raising of the minimum yield, the average yield on many Danish farms has now been raised to 1,000 gallons per cow per year. It is almost as cheap to keep a cow yielding 1,000 gallons per annum as one yielding 400 gallons. Many of our cows do not yield more than this latter quantity. If the Dane can obtain as much profit from two cows as we do from five, it cannot be difficult to understand why he is driving us out of the markets. It is within our province to instruct agriculturists on this and kindred topics, such as the proper and efficient marketing of animals and animal products.

In conversing with our agricultural friends we should press the necessity for the establishment of experimental stations and laboratories. A properly equipped station situated in each province under the control of an efficient director would undoubtedly confer inestimable benefits upon the community. Amongst other questions, there is a wide field open to investigators in connection with that new branch of therapeutics known as serum-therapy, which has already afforded good results, and is full of promise. There never was a time when the scientist was more called for. Of course, I do not by any means suggest that he should in any way take the place of the clinician, for both are essential to true progress—the one, as useful as the other—and I am very pleased to observe that Professor Stockman, of the English Board of Agriculture, appears to think likewise. It is a very happy augury for the future to see a gentleman of his high attainments seeking information and help from the general practitioner, and admitting that the true test of his investigations is their adaptability and usefulness for general practice. It is an acceptance of the truism that the theory of to-day must be established by the procedure of another day, and the success or failure requires the wholesome filtration of discussion before any fact can be satisfactorily established.

In courtesy to the President the discussion was deferred until our next meeting, and Mr. Jordan consented to open it.

On the motion of Mr. Robert Kernohan, J.P., seconded by Mr. John Gault, a hearty vote of thanks to the Chairman was enthusiastically passed.

After the meeting the members were entertained to high tea by the Messrs. Kernohan, which was served up in a very creditable manner by Mr. John Henry, Clarence Hotel, Ballymena, and very much enjoyed.

J. A. JORDAN, Hon. Sec.

PARLIAMENTARY.

In the House of Commons, on Tuesday, Dec. 5.

COAL MINES BILL.

Capt. JESSEL (St. Pancras, S., Opp.) moved an amendment in the third schedule providing that no horse should be taken underground until it was four years old and until it had been tested by a "duly qualified veterinary surgeon."

Mr. MASTERMAN accepted the amendment.

Sir A. MARKHAM complained that the veterinary surgeons had been "log-rolling" hon. members in order to get support for their appointment. His fear was that these veterinary surgeons as well as members of the medical profession might set up "rings" and boycott persons who did not come up to their qualifications.

The amendment was agreed to.

On the motion of Sir F. BANBURY the Schedule was amended by substituting 15 for 20 as the number of horses to be under the care of each horsekeeper.

Mr. BUTCHER (York, Opp.) moved an amendment to provide that every horse that has to be destroyed shall be destroyed with the least possible delay.

Mr. McKENNA pointed out that the Bill required that suitable appliances for the destruction of horses requiring to be destroyed shall be provided and kept readily available for use. It was unreasonable to go beyond that requirement.

The House divided and there voted—

For the amendment	126
Against	195
Majority against	—69.

Mr. BUTCHER moved that no blind horse shall be worked in a mine. He said that many witnesses expressed their opinion that there was serious cruelty in working a blind horse at all, but almost all were agreed that if one had to be worked, it should be led and only used in light work. Inasmuch as in many cases it was difficult and even dangerous to the boys to lead these animals, the only remedy was to exclude them altogether.

Mr. MASTERMAN pointed out that, if these ponies were prohibited from working in the mines, the only alternative was that they would be destroyed. (Hear, hear.) The Royal Commission did not contemplate that with the same enthusiasm as the hon. member for Denbighshire. The Chief Inspector of Mines told him that, in some respects, these blind ponies had many advantages over ponies that had eyes. (Opposition laughter)—the hon. gentlemen who laughed so contemptuously were probably not acquainted with the conditions under which these ponies worked—and that a considerable number of accidents took place through horses which had their sight being frightened by a sudden light. No kind of evidence had been brought before either the Royal Commission or the Committee upstairs to show that there was any cruelty in the use of these blind ponies in mines.

Mr. C. BATHURST (Wilts, Wilton, Opp.) supported the amendment.

Mr. G. GREENWOOD said he was surprised to hear the

Under-Secretary say there was no evidence of cruelty to the horses. Witness after witness examined before the Commission testified that there was cruelty.

SIR A. MARKHAM said he had been associated with the mining industry for many years, and he had not seen any injury caused to a blind horse. Personally, however, he did not object to the amendment, and the Government would do no harm by accepting it. (Cheers.) But he asserted that the horrors which had been described as occurring in mines in respect of the blind horses was untrue. He could show hon. members stone-blind horses that had been working in mines for 20 years, and there was not a mark upon them.

Mr. McKenna said the amendment would cause a charge to be thrown upon colliery owners, but the only colliery owner who had spoken said he had no objection to bearing his share of it. He was prepared to accept the amendment.

The amendment was agreed to.

The Bill was read a third time, amid cheers.

Personal.

MR. W. WILSON, the well-known Veterinary Surgeon, and Mrs. Wilson were recipients of numerous congratulations on Sunday, November 19, on the occasion of their golden wedding, with hearty wishes for continued health and happiness in the evening of their days. Mr. Wilson married shortly after he settled in Berkhamsted. He was first in association with Mr. William Cooper, and afterwards as his successor as veterinary surgeon. During the long period since then Mr. Wilson has been intimately associated with the life of the town and district, and though Captain A.C. Wilson, his son, is now responsible for most of the professional duties, Mr. Wilson is still regularly to be seen driving about the district following his profession. All his sons, we believe, have copied his example in choosing a veterinary surgeon's life, and all are doing well in their profession in different parts of the Empire. Mr. Wilson has been one of the leading Masons of the district for many years, and he has done useful work for a long time as Chairman and Treasurer to the Town Hall Committee. Mrs. Wilson, too, has taken a keen interest in the Girl's High School, of which she has been a governor since its commencement in 1888.—*The West Herts and Watford Observer*.

MR. HAROLD SESSIONS, F.R.C.V.S., of Lawn Lodge, Dawlish, Devon, author of works on "Cattle Tuberculosis," Veterinary Inspector to the Royal Agricultural Society, and for some time connected with the Remount Department, who died at Shortlands, Kendal, on the 10th September last, aged 45 years, left estate valued at £5577 7s. 2d. gross, with net personalty £3807 8s. 2d. Probate of his will dated 17th December, 1908, has been granted to his brothers, Mr. Wilfred Sessions, Kendal, and Mr. Walter Sessions, Cardiff. Power is reserved to grant probate also to his widow, Mrs. Emma Sarah Belinda Sessions. The testator left all of his property to his wife for life, with remainder to his children in equal shares.

OBITUARY.

ROBERT HENRY POTTS, M.R.C.V.S., Calle San Martin 159, Buenos Ayres, S. America. Edin: Jan., 1887.

Mr. Potts died on Nov. 12th. Aged 49 years.

EDWARD LAWRENCE, M.R.C.V.S., Swindon. Graduated, Lond: March, 1882.

Mr. Lawrence died on Saturday, 2nd instant, under tragic circumstances. The meet of the V.W.H. (Cricklade) Hunt was at Highworth, six miles from Swindon, and Mr. Lawrence travelled thither in his motor car.

He found the field on his horse as a move was being made to an adjacent cover, and was apparently in his usual health. He had just made a remark to an old friend, Mr. T. Hooper Deacon, concerning the horse which the latter was riding, when he exclaimed, "Oh! my head," reeled in his saddle, and fell to the ground. Dr. J. J. Powell, who was one of the hunting party, was speedily on the scene, but Mr. Lawrence's condition was clearly very serious, and with all haste he was placed in a motor car and driven to Swindon. Before the end of the journey was reached, however, he breathed his last.

Mr. Lawrence was well known over a very wide district, and was deservedly popular amongst the many sporting people whom he numbered in his friends and clients. He had, strangely enough just retired from the practice which he had followed in Swindon for 35 years, and had built a new residence outside the town in order that he might devote his entire attention to his important stud farm from which horses had been exported to many parts of the world. But the formal transfer to his partner, Mr. Frank Cundell, could not have taken effect until after Christmas. Although not a particularly old man he went to Swindon about 30 years ago. He had suffered two seizures previously. It goes without saying that his tragically sudden death is widely deplored. He was 51 years of age.

THE UPKEEP OF A MOTOR CAR.

Some instructive figures have been compiled showing the cost of running a powerful motor car. A few years ago the West Riding County Council resolved that the Riding Surveyor should be provided with a car to enable him to inspect the county roads and bridges more easily. This step was resolved on in the interests both of economy of time and money. No doubt the Surveyor's car covers great distances, and since the cost of its upkeep has never been challenged at the meetings of the County Council during the past year, it may be safe to say members do not regard the expenditure upon it as excessive. But it will surprise some people to learn that for the nine months ended last December the cost of running this one car—not taking into account the wages of the chauffeur or repairs to the house in which the vehicle is kept—has been no less than £561 13s. 7d. Details showing the cost of running the car for the last three quarters are appended:—

JUNE QUARTER.		£	s.	d.
Tyres, repairs, etc.,	Walter Judge	34	2	2

Total		£213	15	4

These items are taken from the County Council's own accounts as presented quarterly, so so that they may be regarded as official. Speaking roughly, therefore, it may be assumed that the West Riding Surveyor's car costs in renewals, repairs, and petrol anything between £700 and £800 a year.—*Yorkshire Post*.

VETERINARY LECTURES.

Sir,

My attention having been called to one of Mr. Mason's "great lectures" published in *The Leinster Leader* (a paper which I would not otherwise have seen) it struck me that if you could afford it space in *The Record* it might interest the profession and help to "spread the light" for the benefit of English and Scotch farmers, and thus place them on equal footing with their Irish brethren. It may also induce other practitioners here to secure and send you copies of Prof. Mason's orations delivered in other parts of the country, and enable us by a study of the collection to determine whether the Professor's lectures may not be all sufficient for stockowners' veterinary wants in the future, so that we may look out for some other mode of making a living, and

guard against the error of wasting money and destroying our children's prospects by sending them to study veterinary medicine.

Public lectures may not always contain all that is given away, for although some lecturers of this kind may be reserved in the way of giving extra hints, certain it is that further information will be solicited in the after lecture time.

It is all very fine to say "Oh! there are grand fields opening up in the way of research, etc., etc." The glory of bacteriology won't keep the pot boiling for the general practitioner. Between the scarcity of horses and their now few abnormalities, owing to sound breeding, there is little else left for us to do after what the professor is catering for in his lectures to the public.

It may be said that farmers will not be able to give the hypodermic injection which Mr. Mason prescribes, but I know differently, having observed how the chemist supplies and instructs him how to use the hypodermic, intratracheal, and other instruments.

Undoubtedly these lectures will gain for the Department of Agriculture much appreciation from farmers, many of whom set but little value on other branches of the Department's efforts. Were we satisfied that animal ailments would be as well cared for by their owners, we should not grudge that most deserving class—the farmer—the benefit of the turn which things are taking, but from our experience of the difficulty of successfully treating the patient which cannot speak, we know otherwise, and that were we cut out to-morrow the last stage would be infinitely worse than the first, hence the questionable advisability of shouldering us out.—Yours truly,

M.R.C.V.S.

P.S.—I would be glad if the subject would draw forth comments from some of your correspondents.

[Want of space prevents our reprinting the newspaper report referred to.—Ed.]

Practices for Disposal

BUCKS. A good opportunity for a young, qualified V.S., to secure a well established practice, represented as returning (cash) £300 p.a. on average for 16 years. Vendor retiring from profession. Good 8-roomed house and garden, stabling, etc. at £30 p.a. To effect early sale vendor will accept £100. PR. 188.

SOUTH MIDLANDS. A good-class practice in a first-rate sporting district is for immediate disposal. Satisfactory reasons for relinquishing. Returns represented as being over £450 p.a. PR. 119.

EASTERN COUNTIES. An old established practice in good agricultural district is for disposal. Represented as returning about £450. Low inclusive price for quick sale. Nice house and stabling, large paddock. PR. 118

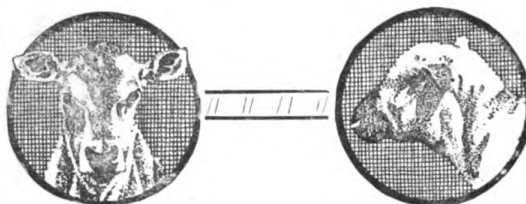

HAMPSHIRE. A partner required for old established practice in fashionable sea-side resort. Returns represented as close on £700. Premium for half share £300, which can be paid by instalments if necessary. PR. 434

CHANNEL ISLAND. An opportunity for acquiring the nucleus of a practice represented as returning about £175 p.a. Great scope for increase. Easily worked at little expense. An offer of about £50 would be accepted for immediate sale, vendor having secured an appointment. PR. 120.

Many Practices are Bought & Sold through our Agency without ever actually coming into the market.

PRACTICES FOR DISPOSAL

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

HOME COUNTY. Receipts £350 to £400 per ann. Rent £35. Premium required £200.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

IRELAND. Partner wanted to take charge of practice returning about £1200 per annum. Rent of premises £82 per annum inclusive. Contracts produce over £400 per annum. Practice has been in present hands 12 years. Premium required for half-share £500

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended

LONDON, S. Practice producing over £1000 per annum. In present hands nearly 40 years. Good house, with stables, kennels, etc. rent £70. The practice is principally dog with some horses and dairies. Vendor retiring. Premium one years purchase.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

SCOTLAND. Returning over £300 per annum. Expenses very low. Premium £120, or nearest offer.

YORKSHIRE. Receipts 1910 £332. Rent £19. Premium £300.

These will be received up to Thursday morning.
Five lines or under 2/6 (exclusive of heading): for two insertions 4/-; for three 5/-; after three 1/- each.
Each line above five—first insertion 6d; after first 3d.
Average—seven words in a line.

These Advertisements will not be inserted unless prepaid, and if replies are to be received at this office an extra sixpence must be included.

ROYAL COLLEGE OF VETERINARY SURGEONS

THE Register of Veterinary Surgeons, 1912, is now being prepared for the press. All alterations in address, etc., should be communicated to the Registrar not later than December 23rd.

10 Red Lion Square, London, W.C.

New Zealand

TWO Qualified Veterinary Surgeons required for service under the New Zealand Government. Salary £300 per annum and regulation travelling allowance. For further particulars and application forms apply to The High Commissioner for New Zealand, 13 Victoria Street, London, S.W. enclosing stamped envelope.

Commonwealth of Australia

APPLICATIONS are invited for the position of Meat Inspector from qualified veterinary surgeons with practical experience and expert knowledge of meat inspection.

The officer chosen will be attached to the office of the High Commissioner for Australia. Salary £600 per ann. Applicants must state age, and forward copies of testimonials.

Applications to be addressed to the Official Secretary, Commonwealth Offices, 72 Victoria Street, Westminster, and will be received up to December 18th, 1911.

As Assistant

ASSISTANT (1899), steady; will furnish references. Would act as locum. Address, 3117 V.R. 20 Fulham Road, London, S.W.

For Sale

HIGH-CLASS, old established, suburban practice, mixed (chiefly dog), in good neighbourhood: held on lease: brick built kennels. Price £300, to include drugs, instruments and fittings. Well stocked surgery, good introduction, owner retiring. Bargain. Address, 3125 V.R., 20 Fulham Road, London, S.W.

As Manager or Locum

M.R.C.V.S., disengaged Dec. 31st, desires position as manager or locum. Experienced, abstainer and thoroughly reliable, recent references. Address, 3127 V.R. 20 Fulham Road, London, S.W.

As Assistant

VETERINARY Surgeon, aged 27, desires post as assistant, with view to partnership or succession, in good-class practice. Experienced in all branches: highest references. Interview. Address, 3128 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: In bottles, 6d. per dose; minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad), 1s. per dose.

Locum Tenens

MR. WALTER G. GREEN, M.R.C.V.S.

"Rosenheim,"
Boscombe Park,
Bournemouth.

As Locum or Assistant

FINAL year student (29) offers services. Sound experience in town and country practice: Ride and drive horse or car. Free Dec. 15th. S. H. L. Woods, R. V. Coll., Camden Town, N.W.

Wanted

FOR 3 months or longer, class C or D student or young man who has seen practice and can dispense. Terms board, lodging, laundry and 10/- per week. Address, 3112 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

FOR country practice, must be able to do standing operation, and well up in cattle practice. State age, references. Sign bond. Address, 3121 V.R. 20 Fulham Road, London, S.W.

As Assistant or Manager

WANTED post as assistant, locum or branch manager, preferably with view to partnership. Good experience town and country practice. Excellent references. Address, 3122 V.R. 20 Fulham Road, S.W.

For Disposal

AN exceptional opportunity occurs for a suitable gentleman to acquire a very old-established practice near London. Returns are about £1100 per annum, and the practice has been in present hands over 30 years. A bona-fide purchaser will be given every opportunity for investigation. Satisfactory reasons for sale. References given and required. Premium, one years purchase. Address, 3126 V.R., 20 Fulham Road, London, S.W.

As Assistant

M.R.C.V.S. (26) requires assistantship in busy mixed practice. Good at parturition: castration standing. Good testimonials. Address, 2129 V.R. 20 Fulham Road, London, S.W.

Practice or Partnership

ADVERTISER, who has £1200 on hand, will be pleased to have particulars of practice or partnership for sale up to that amount, confidence respected, no intermediaries. Address, 2114 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

National Veterinary Benevolent and Mutual Defence Society.

ALL Members of the R.C.V.S. are eligible for membership, and on payment of an entrance fee of one guinea, and an annual subscription of half-a-guinea are entitled to all benefits.

Copies of rules, and further information may be had from

G. H. Locke, Hon. Sec.
Grosvenor Street, Oxford Rd., Manchester

For Disposal

WARWICK, freehold house (or lease) 20 Jury Street. Veterinary surgeon's business carried on upon premises for over 50 years, in main street, country town, good hunting district. 3 reception, 6 bedrooms, bath, large yard in rear. 5 loose boxes, stall, large shoeing forge, saddle room, loft, surgery. Ledbrook, Solicitor, Warwick.

For Disposal

COUNTRY practice, good house, surgery, stables, and garden. Returns £150. Rent £24 per ann. Small premium. Address, 2127 V.R., 20 Fulham Road, London, S.W.

Wanted

RELIABLE, qualified assistant for an extensive mixed practice. State age, height, and give references. Salary £100 per annum all found. Address, 2123 V.R. 20 Fulham Road, London, S.W.

For Disposal

GENUINE country practice, market town, Yorks. C.C. appointments. Receipts about £300, introduction. Must be sold, £50. Address, 1123 V.R. 20 Fulham Road, London, S.W.

As Assistant or Locum

M.R.C.V.S., (1909), desires position as assistant or locum: good horseman, excellent references: Address, V.S., 39 Little Heath, Old Charlton, Kent.

Partner Wanted

WANTED a thoroughly reliable, practical, qualified married man as partner in high-class country practice. Full particulars in strict confidence on application. Only bonafide applicants will be entertained. Address, 1121 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

M.R.C.V.S. (36) recovering from serious illness, desires light work, e.g. attending yard cases, walking visits and dispensing. Small salary. Apply, A. A., Stewart, Solicitor, 205 Hope Street, Glasgow

Replies to Numbered Advertisements

WHEN replies to several of these advertisements are sent to this office at one despatch, it is not necessary that they should be stamped separately: they may be enclosed in one envelope, but should be marked outside "Replies."

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Gregg's Tracheotomy Tube

MADE in one piece (improved hinged flanges.) The best and the cheapest Tube on the Market. Used by all up-to-date Veterinary Surgeons. Satisfaction guaranteed. Price 15/- Robertson & Co., Victoria Square, Belfast.

CHEAP BOTTLES.

A large quantity of named medical bottles (these have various chemists' names on and washed ready for use)

2oz., 3oz., 4oz., 6oz. and 8oz. at 5/6 a gross.
10oz., 12oz., and 16oz. at 7/- a gross.

Cash with order. Carriage paid on £3 orders within 70 miles, and on £5 orders any distance.

Other bottles and jars quoted for.

Royal Veterinary College, London.

(Founded 1791.)

Principal and Dean : Professor **SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.**

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities, etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.), which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts, and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 7th, and terminate on Friday, November 29th, 1912.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1223.

DECEMBER 16, 1911.

VOL. XXIV.

PUBLIC SUBSCRIPTIONS.

Many men annually spare a little from their incomes towards the needs of others. Veterinary surgeons often do so, but do not always remember that there are objects worthy of support within their own profession. At the end or beginning of a year we should recall three such objects which especially deserve and need annual subscription from veterinarians.

One is the R.C.V.S. itself. Three weeks ago we noted that Mr. G. Garnett had repeated his example of last year by sending a second year's subscription to the College funds. Others have since followed suit, and many more should do so. This, as we have said before, may well be regarded as simply anticipating the effect of the pending Bill. Under the present Parliamentary conditions a long time may pass before the Bill even obtains a hearing; its main provision is becoming more and more urgently needed, and should be established as a custom amongst us before it becomes law.

Next we have the International Congress Fund. The development of international veterinary communication, and the credit of the profession in this kingdom, are alike involved in the success of the great Congress to be held in London in 1914. But to ensure that success, a sum such as our members have never yet raised will be required. It must be raised within a comparatively short time, and can only be raised by the united efforts of the profession. We cannot, therefore, subscribe too soon.

Both these are temporary objects for support; and their claims are all the more urgent because temporary. A third and permanent object lies in our benevolent societies, which have never yet received their due meed of support from the profession. At this time of the year especially, members whose incomes will permit of disbursement may well spare a little to help others less prosperous than themselves.

Practically all of us could afford something to to one of these three objects. Most could afford a little help to each.

LIEUT.-COL. G. H. EVANS, C.I.E.

In the long list of Indian Coronation Honours, we are glad to see that our profession has been remembered. The distinction just conferred upon Lieut.-Col. Evans marks individual good work, but it also has a wider significance. Bestowed at this time upon the officer directing the Civil Veterinary Department, it really amounts to a Governmental recognition of the valuable part which that Department is performing in the development of India.

VOMITING IN THE HORSE.

I was called one evening to attend a seven-year-old cart mare suffering from colic. She seemed in considerable pain and was rolling from side to side. Adopting the usual routine treatment, I first ascertained the condition of the bowels, and finding the rectum full of hard, dry faeces, very little of which had been passed during the day, I removed them and gave a warm soap clyster. One grain of eserine was injected, but obtaining no result in half-an-hour I gave a 5vi. ball.

During rectal examination I found the bladder very distended and consequently passed the catheter and drew off a large quantity of urine. Several anodyne draughts were left to subdue pain, and consisted of Chlorodyne and Ess. menth. pip. The following morning she was no better and continued in this unsatisfactory state all day, passing no faeces, so I administered a pint of linseed oil. Towards evening she began vomiting through the nose and mouth, which continued all night. The diagnosis then, was ruptured stomach, and the prognosis speedy death.

She never at any time passed any faeces, and the water had to be drawn off. Death ensued at 12 o'clock on the following day.

An autopsy was made in the afternoon which revealed stomach and intestines greatly distended with food, but the stomach and oesophagus were quite intact, and I was for a moment at a loss to know the cause of the vomiting—so rare in the horse. There was, however, discovered a big rent in the caecum and third portion of large colon.

Colic in the first place had evidently been due to impaction of the third portion of colon from too much food and lack of exercise—for the animal had been idle a fortnight with maulenders. The ingesta had been rendered quite fluid by the ball and oil, and recovery would undoubtedly soon have taken place but for the rupture.

HAMILTON KIRK, CLASS D.

Dr. Thurston Holland, of Liverpool Royal Infirmary, an x-ray pioneer in this country, at a meeting in connection with the Port Sunlight Literary and Scientific Society, gave an interesting account of the history of the invention and its present field in surgery.

It was his very good fortune to be one of the first men in England to use x-rays in a practical way. His friend Robert Jones was quick to recognise the possibilities of the invention. He consulted Prof. Oliver Lodge, then connected with their University, as to the locating of a bullet supposed to be in the hand of one of his patients. They rigged up an apparatus, and after repeated trials obtained a plate showing an undefined but convincing shadow of the bullet just before the joint of his wrist.

ABSTRACTS.

SENSITISED VACCINE IN HÆMORRHAGIC SEPTICÆMIA.

Major F. S. H. Baldrey, I.C.V.D., describes (*The Journal of Tropical Veterinary Science*, Vol. VI., Part III.) a method of protective inoculation for hæmorrhagic septicæmia devised by him, the object of which is to combine a protective serum and a vaccine. The advantage of this is that the negative phase produced by the vaccine is eliminated, and immediate immunity results from the operation. There are special reasons rendering such a method peculiarly useful in India. Generally inoculation is practised during the prevalence of an outbreak, and the early immunity is of great value, as it enables the vaccine to be given without fear of lowering an animal's normal resistance. Again, there is still much native prejudice against inoculation methods in India, which deaths after inoculation of course increases; while it is almost impossible to keep animals away from possible infection during the period necessary for immunisation if a vaccine alone is used.

The theoretic principle of Baldrey's method is to combine the antigens of the vaccine with the amoceptor of the protective serum in the absence of complement. He details the technique adopted in preparing the vaccine, of which it may merely be said that it is even more difficult and complex than such laboratory procedures usually are. He also tabulates and explains his experiments, which were performed upon twenty-four bulls, and which yielded highly promising results. In the author's own words—"The percentage of deaths on animals protected by sensitised vaccine are 28.4 per cent. if tested in less than six days after vaccination. This is very good as compared with an unsensitised vaccine when the percentage of deaths is almost equal to the controls in the period under ten days. The percentage of deaths in testing after six days and up to one month is 22.2 per cent. This is but very little higher than one would get from a plain vaccine after ten days, but the disadvantage is outweighed by the advantages gained in obtaining an immediate immunity."

Baldrey's final conclusions are (1) That a sensitised vaccine for hæmorrhagic septicæmia is possible. The sensitising to be done with a heated specific serum, otherwise bacteriolysis occurs. (2) That it gives immediate immunity, thus obviating the objectionable negative phase. (3) The method of manufacture is somewhat tedious and requires infinite care in manipulation, but is a practical laboratory one. (4) The method is particularly suitable to India, for reasons already given.

These conclusions are with regard to the method as it stands at present; but Baldrey remarks that, as these experiments were the first of the kind performed in India, and the time at his disposal was limited, it is possible that the technique may yet be further improved, and better results obtained. Considering the growing importance of hæmorrhagic septicæmia in India, the research seems to be an extremely valuable one.

INFECTIOUS OSTEITIS OF HORSES AND CATTLE.

Baumgartner (*Journal de Méd. Vét. et de Zoot.*) gives an account of this condition, and summarises his conclusions as follows:

(1) An osteitis and an osteo-myelitis, both very painful, and occasioned by the invasion of the bacterium of necrosis (either alone or in symbiosis with a Gram-positive coccus) are rather frequent in horses and oxen.

(2) This infection causes a lameness, which is especially very pronounced when the animal bears weight upon the limb. It gives rise to a frequent pulse, and sometimes to fever. It is compatible with a good digestion.

(3) In some cases, abscess formation occurs.

(4) The disease has an extremely destructive action upon the osseous tissue, without the formation of secondary exostoses. An augmentation of volume of the bone, therefore, is never encountered in this condition. Sometimes the bone is sensitive to pressure.

(5) The disease is always of long duration.

(6) Treatment by iodine has a great influence upon recovery.

(7) Hitherto cases of this disease have often been set down as rheumatism—*Annales de Méd. Vét.*

GELATINE AS A HÆMOSTATIC IN VETERINARY SCIENCE.

Prof. Diego Blasi, of the Veterinary School of Montevideo, gives (*Rev. Gén. de Méd. Vét.*) some details of the use of gelatine as a hæmostatic, and of his own experience of it in animals.

The most favourable methods of introduction are by subcutaneous and intra-muscular injections. In some cases local applications (tamponnages or irrigations) may be indicated.

Needless to say, the gelatine has no influence upon the cause of the hæmorrhages. It acts differently upon hæmorrhages of every description from the lung, kidney, bladder, intestine, uterus, etc. As a general rule, it is preferable to the other hæmostatics, all of which possess a rather high degree of toxicity, and are inconstant in their action.

The author has employed gelatine in the following cases: epistaxis of traumatic origin (3 horses and 2 dogs); ulcerous gastro-enteritis and hæmorrhagic enteritis of the dog (7 cases); parenchymatous nephritis of the horse with hæmoglobinuria (2 cases); metrorrhagia in the bitch (4 cases); accidental and operative traumas (8 cases); and anasarca of the horse with petechiæ upon all the mucous membranes (4 cases). The results have always been superior to those furnished by the usual hæmostatics (hydrastis, hamamelis, ergotin.)

In paroxysmal hæmoglobinuria of the horse, gelatine has no action.

For the *large* animals the following formula may be employed:

Pure Gelatine (Merck's)	20 parts.
Pure carbolic acid	1 "
Physiological serum	1000 "

This is injected hypodermically. The solution keeps well, from its contained carbolic acid; its injection does not cause pain, and it is not necessary to place it in a water bath at the moment of employment. In the horse, from two to four litres (=3½ to 7 pints) of this fluid may be injected in 24 hours.

Another formula, which is rendered more active by the addition of ergotine, is recommended in hæmorrhages from the uterus. It is as follows:

Pure Gelatine (Merck's)	40 parts,
Ergotine	5 "
Physiological serum	1000 "

This solution must be kept fluid in a water bath during its injection. Two to three litres (3½ to 5½ pints) may be injected in a day.

For small animals, the following solution, which is commonly employed in human practice, is recommended:—

Pure Gelatine (Merck's)	16 parts.
Pure Chloride of sodium	3 "
Distilled water	400 "

This must be melted in a water bath, filtered carefully, and sterilised. From 50 to 150 grammes (= approximately 3iiss. to 3v.) are injected under the skin or into the muscles, the solution meanwhile being kept in the water bath.—(*Annales de Méd. Vét.*) W. R. C.

PERCUSSION DIAGNOSIS OF PLEURISY.

Pitres' halfpenny sign is a good means to reveal the presence of pleural effusion. An assistant percusses a penny placed flatways between the inter-

costal space with another held perpendicularly. The practitioner auscultates at a point diametrically opposite to the healthy side of the chest percussed. The ear of the auscultator perceives the striking sound, which is increased by the pectoral resonance. In the hepatised region the resonance is deadened as if by a layer of plaster. On an exudate, even if slight the echo is retarded and modified in its tone, which resembles that obtained by percussing a half empty cask. The modification of the tone is distinctly clear on a level of the surface of the liquid (halfpenny sign).—*Bulletin de Soc. Cent. Méd. Vét.* 30th September, 1911.

[Compare this with note on "Tracheal Percussion" in *The Veterinary Record* November 18, 1911, p. 309.]

Auto-serotherapy in Pleurisy.—Inoculation into the subcutaneous areolar tissue of the pleural effusion withdrawn by thoracentesis has given Marchal and Séjournant successful results in the treatment of pleural in the horse. In order to obtain good results one must operate early in the malady and inject small doses of the freshly withdrawn exudate. H. G.

The President of the Council of the French Parliament has conferred the "medal of honour of epidemics" on M. Dubois for his studies on "The Prophylaxis of Malta Fever." A translation of this author's paper on the subject appeared in the September number (1911) of *The Journal of Comparative Pathology and Therapeutics*. It is a paper full of interest and of instruction, especially to those practitioners who have to do with goats and sheep.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Dec. 11, 1911
 Note.—The figures for the Current Year are approximate only. * As Diseased or Exposed to Infection

SCOTTISH METROPOLITAN VETERINARY MEDICAL SOCIETY.

A meeting was held in the Royal (Dick) Veterinary College on Wednesday, Oct. 25th. The President, Mr. James Peddie, occupied the chair.

The minutes of the last meeting were read and confirmed.

The SECRETARY intimated letters of apology from Messrs. Inglis, J. W. MacIntosh, Robson, Hamilton, and Prof. J. R. McCall.

CORRESPONDENCE.

The SECRETARY read letters from Prof. Woodruff and Mr. Wm. Shipley asking for subscriptions to the Kirk Appeal Fund and the Victoria Veterinary Benevolent Fund respectively.

The CHAIRMAN said that they had better take the letters from Prof. Woodruff and Mr. Shipley together, because they were both asking for donations for their funds. The Council met before the meeting and decided to put before the meeting a recommendation that they should give one guinea towards Mr. Kirk's appeal fund and also one guinea to the Victoria Benevolent Fund. It was open for their consideration now as to what they should do in the matter.

It was agreed to subscribe one guinea to each fund in accordance with the recommendations of the Council.

The CHAIRMAN said that the next matter was a letter from Prof. Gofton with regard to the amalgamation of Societies. He supposed as they had already given a definite opinion on the case, all that was necessary was that someone should formally move that they agreed to the conditions. He had much pleasure in moving that the Society become affiliated to the National Veterinary Association in accordance with the amended rules.

Mr. AITKEN seconded, and the motion was carried unanimously.

NEW MEMBERS.

Messrs. J. G. MACGREGOR, Greenock, and M. MACKAY, Kelso, who were nominated at the last meeting, were elected members of the Society, on motion of Chairman, seconded by the Secretary.

Prof. AINSWORTH WILSON was nominated for membership by Mr. Henderson, and seconded by Mr. R. Reid.

Messrs. A. MACKENZIE, Kirkcaldy, DAVIDSON, Edinburgh, and J. BASIL BUXTON, Edinburgh, were nominated by the Secretary, seconded by the President.

Mr. MATTHEW, Selkirk, was proposed by Mr. R. Reid, seconded by Mr. Hannay.

ELECTION OF OFFICERS.

Prof. GORTON said that he wrote the President some time ago asking to be allowed to renominate him to fill the President's chair for another. It was with some very considerable hesitation that he had consented to re-nomination, but he thought Mr. Peddie had been persuaded that it was almost his duty to continue in office, and that his place would be somewhat difficult to fill should he retire at the present time. He had therefore consented to stand, and he now had much pleasure in nominating Mr. Peddie as President for next year.

Mr. REID seconded, and the motion was carried unanimously.

The CHAIRMAN said he would like in a word to thank them for the honour they had done him in electing him to preside over the Society for another year. The feeling of hesitation which he had was not due to a lack of interest in the Society, but to the increasing difficulty he found in attending the meetings. One who held a presidency of the Society did not like to absent himself from the meetings if it were at all possible for him to attend, and it occurred to him that someone could have been found to attend the meetings to whom it would be

easier than it was for him. It would not have meant, if he had relinquished the chairmanship, that he would have lost interest in the Society, but he would have felt he was not bound to attend the meetings so religiously. Seeing they had agreed to his nomination he would do his best to pilot the Society for another year. He would ask them to co-operate with him as heartily as they had done in the past.

As the Secretary had said, they could do with a greater number of members. He pleaded with everyone to try to get their friends within the radius of Edinburgh to join them. There is no doubt that unity is strength, and the greater number of members they had the better it would be for the Society. He hoped they would have a prosperous year and that the Society would be found in a prosperous condition at its close.

Vice-Presidents.—Messrs. R. Reid, J. Riddoch, and Prof. Dewar were elected on the motion of Mr. J. Cameron.

Auditors.—Messrs. J. Henderson and J. Riddoch were re-elected.

Hon. Sec. and Treasurer.—Prof. Gofton was re-elected on the proposition of the President, seconded by Mr. Henderson.

Council.—Messrs. A. A. Baird, Cameron, sen., Aitken, junr., and Principal Bradley were re-elected, on the motion of the Secretary.

THE INTERNATIONAL CONGRESS.

The SECRETARY said that he wished to mention a matter which, strictly speaking, was not a part of the business of the meeting, but since all the societies had been appealed to in connection with it he thought it would be wise to bring it forward now. It was the International Congress of Veterinary Surgeons, to be held in this country in 1913 or 1914. It had been intimated that about three thousand pounds would be required, of which one half would have to be raised by the members of the profession in this country. This Society was not in a position to give a large sum, but he thought they might give a small sum and repeat it next year if funds permitted. He moved that the Society subscribe a sum of two guineas.—Agreed.

THE LATE MR. CHARLES CUNNINGHAM.

Mr. CAMERON rose to propose that a letter of condolence be sent to the relatives of the late Mr. Cunningham, of Slateford. For many years Mr. Cunningham had been a member of the Society, and he was a close neighbour and a very prominent member of the profession. The reminder he had received was the name Cunningham cut out on the desk in front of him. It was prominent there, and reminded him of the many pleasant memories of Mr. Cunningham, and his able assistance to the profession, particularly from a Scottish point of view.

The CHAIRMAN, in seconding Mr. Cameron's motion, said that the late Mr. Cunningham was an able and cultured man, very genial and kindly. He had nothing but pleasant recollections of him, and he thought it would be gracious on the part of the Society if they were to move a vote of condolence with the family and send the letter. He asked the members to pass the resolution upstanding. The motion was carried in silence.

ERYSIPELAS.

By Mr. JOHN CAMERON, M.R.C.V.S., Berwick.

In choosing a subject for discussion at this meeting, two alternatives present themselves—is the subject to be elaborated in full detail; or should the principle features of the subject only be stated, and each one asked to contribute in building up a more complete structure. Of these two I think the latter is on many grounds to be preferred. I am quite aware that many

prefer to be crammed with spoon feeding; they forget the old truth that there is "a giving which does not impoverish and a withholding which does not enrich."

Again, should the subject be a common one, such as equine surgery of the foot, or one which has received comparatively little attention in veterinary literature, such as erysipelas? I have decided on the latter—Erysipelas.

In Scotland, in the vernacular for generations past, it has been "The Rose." In England it has been known as "St. Anthony's Fire."

It may be defined as a specific, contagious inflammation of the skin, due to streptococcal infection, accompanied by constitutional disturbance. In one respect its history is like that of swine fever and tuberculosis, in that it was known to be contagious long before the infecting germ was isolated and determined. The special micro-organism—a streptococcus—was first successfully isolated and proved by Fehleisen. In his opinion this streptococcus had characteristics which distinguished it from the streptococcus pyogenes. Other bacteriologists who have investigated the subject do not support that conclusion. They hold that the germs are identical, and that any clinical differences can be accounted for by variations in the virulence of the organism, variation in the site of inoculation, also the constitution and resisting powers of the subject.

This same streptococcus may also produce erysipelas or puerperal fever, according to the condition of the subjects.

There is no need for a large wound, as a microscopic abrasion will be sufficient for inoculation. For many years now I have observed that when one gets one case of erysipelas one frequently gets at about the same time other two or three cases. Sometimes on such occasions one will also hear of persons being affected with erysipelas. It seemed as if atmospheric influence had something to do with its development. On many occasions I have observed cases occurring in a leg, the animal rather thin, and working full time, and the weather was cold, wet, windy, stormy, severe.

In the human subject the infection may be carried by the doctor, the nurse, by instruments, bedding, etc. The infection of some rooms and places has become chronic. It therefore becomes our duty to be careful and see that we do not act as agents in disseminating the disease. An important feature of the disease is its disposition to periodic attacks on the same subject. These should be watched for and anticipated by preventive treatment. In the human subject many persons who have only had a mild attack of this disease, and who are not aware that it is a blood poison disease of a relapsing and increasing disposition, think of and treat it lightly, often with prolonged and fatal consequences. I hold that it is equally so in animal practice. I go further, and say that I believe a wrong diagnosis is many times made between cases of "weed" and erysipelas.

In case of "weed" or supposed "weed," we are frequently not consulted. It is a thick leg, and it is presumed that it is quite correct to give all swelled legs the same treatment. Take a typical case of "weed" with swelling beginning on the inside top of the thigh, extending downwards, with full, strong, bounding pulse. One gives at once a good purging dose, fever draught, and may—if in the early stage—bleed freely. One may, thereby, expect good prompt results. But, if the case has begun to swell at the fetlock or hock, the swelling extending upwards rapidly, the pulse quick but small, and the temperature high—higher in proportion to the other symptoms and the length of time affected—in such a case of swelled leg the previous line of treatment for "weed" will not give the same improvement. There are still owners of horses and experienced attendants who have often noted the excellent results arising from bleeding in a case of "weed," and they often expect and

ask you to bleed the case in hand. If it is an early case of real "weed" I homologate their desire for blood-letting. But if the case is of the nature of erysipelas I consider it my duty to point out that every swelled leg is not a case of "weed." That this case is different, and bleeding would be decidedly injurious.

"Thick legs" also occur under very different conditions. I do not need to enumerate the typical circumstances which give rise to "Monday morning disease." On many occasions we have a sudden swelled leg in a horse whose general condition is "below par," and which has been performing a full amount of regular work; time, middle of the week; weather, severe. This is not a case of "weed." By pointing out to the owner these differences one is able to convince him that we are exercising careful, sound judgment in not bleeding the case, and in other differences of treatment. We would also be careful to let him know that relapses are to be expected, and that the rate of progress and prognosis cannot be given with the same confidence as in some other conditions. The treatment of this disease, historical and otherwise, is not creditable to veterinarians. It is a disease with a long, broad history, and one which has caused much illness and death in the human subject. The late Finlay Dunn says:—"Rarely occurring in horses." Gamgee: "Seen more often amongst sheep and dogs than any other animals." A recent author, the late Professor Axe, under the index title Erysipelas, says: "The worst case he ever saw arose from using too freely the singeing lamp." That is all. My experience extending over many years has been that erysipelas is a common disease in the horse.

The incubation period is variable. In the case of pure inoculations it varies from 15 to 60 hours; but three to eight days is the usual period. We frequently have the infection and development of erysipelas in connection with wounds, and especially in the early period. After a few days have passed, and nature has supplied the parts with leucocytes and other micro-organisms, it would appear that the infection of erysipelas is not so easily accomplished. It is, therefore, in the early stages of all wounds and bruises that antiseptic treatment, general care and cleanliness, both of the animal and its surroundings are specially called for and are specially beneficial.

Many owners of animals have a dread of tetanus, but they do not dread erysipelas or other blood poisons as they should do. Very often it is only after the large, rapid, thick edged swelling has developed that the veterinary surgeon is sent for. It will then be our duty to impress on the owner and his assistants the great need for a much higher standard of cleanliness in the surroundings and housing of animals suffering with broken and bruised surfaces, including a more liberal allowance of disinfection to the stall and stable generally, if the case is to progress without interference from blood poisons. They must also be made to understand that this kind of swelling is due to a blood poison, and that internal constitutional treatment is quite as necessary as external treatment.

Wounds and bruises having existed a few days, we may have a sudden, extensive, thick-edged swelling of the surrounding parts, with a high temperature. The symptoms, duration, and final results of an attack of erysipelas vary very much. The onset and development of the disease is always sudden, and if the treatment is prompt and appropriate the inflammation will abate, and the exudate be absorbed comparatively early. But unless everything is favourable, recovery and reduction of the parts are often prolonged.

In the horse we also have the characteristic relapses of this disease frequently and fully demonstrated. Although the attendant's report and the appearances are favourable, it is wise to count the pulse, and especially to take the temperature. An increase of tempera-

ture is sure to have its corresponding increase or extension of swelling next day. Frequently the relapses do not last more than one or two days, and although the swelling has increased the temperature is again much reduced. Its erratic disposition is also prominently displayed by new developments in other and distant parts of the body.

On some occasions the exudation in the areolar tissue beneath the skin is extensive, and very rapid suppuration may take place. These parts, if not lanced, will soon burst, leaving a large ragged opening. The discharge contains very little real pus but more flakey, turbid serum, and broken down areolar tissue. Although this process looks serious it has the advantage of quickly removing the effusion, and the parts—such as the leg—are sooner restored to a moderate size and usefulness. In more serious cases the inflammation and suppuration become deeper seated, and there may be difficulty in giving it free exit, especially if joints, tendons, or ligaments are involved. In such cases the pain and lameness may be very severe and prolonged with prominent deformity of structure. The relapses of the invasions of other parts may be so severe, and cause so much destruction of essential parts as to cause the death of the animal.

I shall never forget a case which began on a shoulder blade, arising from a punctured wound. It ended in gangrene of the tendons and ligaments of a hind foot; the flexor tendons sloughing through entirely, and the toe looking straight up. Destruction of the horse—a valuable one—thus became necessary.

TREATMENT.

Serum treatment.—Now-a-days, I suppose, it would be a great omission to pass over the serum treatment in constitutional diseases. On this subject I have no light or leading to give you. At previous meetings some of our younger members have given us their experience of serum treatment in other diseases, so I shall depend on them on this occasion. So far as I understand the subject, the serum treatment in erysipelas in the human subject has not been attended with any success worth mentioning.

Internal.—In most cases a purging dose of aloes, or aloes and calomel, or aloes with a little linseed oil, and tr. ferri perch. or turpentine should be given. This to be followed up with repeated doses of turpentine, Tr. ferri and Ol. lini, *aa* ʒi in a bottle of gruel. Also repeated doses of Colchicum and Saline diuretics. Also Hyposulphite of soda frequently repeated. Sometimes a variation may be made with a few doses of Iodine and Iodide of potassium. In my experience I have had good results with Tr. ferri. and Ol. tereb. Even if the case is making fair progress one will be wise to continue giving periodic doses of these. If not, one need not be surprised to find a sudden and severe relapse which will set the case back for at least a few days. These relapses may be so frequent and so severe that we will not attain success, unless we have in hand a large supply of patience and perseverance.

External.—If cleanliness and disinfection have not been well attended to before the appearance of the disease, I would prefer a thorough wash with soap, warm water, and a disinfectant, such as lysol, as a first application. Then dry the parts and dress all over with a soothing antiseptic dressing, such as glycerine, water, lysol, and belladonna or opium. Sometimes an oily liniment containing a preparation of lead is preferable. Ointments are on some occasions to be preferred. The special agent may be boracic acid or ichthyol, the latter being recommended in the human subject. In addition the parts may be well dusted with disinfecting powder, or starch powder with an active agent added. Even a good dusting with flour alone is considered beneficial.

With the object of stopping the progress of the derma-

titis, many expedients have been tried in the human subject, but with little success. Painting the parts in advance with glycerol of iodine may be tried. When one has large deep seated abscesses, they will require to be often and thoroughly injected and washed out with an antiseptic, stimulating wash. A frequent change in the active agent in these washes and lotions is, I think, desirable.

About 18 months ago I had a most severe, prolonged, relapsing case where there were at least three such cavities, and they had inter-communication. On different occasions I injected them from the under opening—side of the knee—pumping in the fluid with a syringe used for injecting liquids into cows' udders. I injected a full litre bottle-full, the whole being retained, and the animal walked on one occasion about thirty yards before any of it came out. That case consumed a vast amount of patience and perseverance, but we were rewarded at last with real success—worth the expenditure.

To finish up some of these successful cases one will require some good iodine blisters and a run at grass. Again, I say, remind the owner that these relapses and prolongations are the nature of the disease, and that in many cases they cannot be cut short or prevented, either in man or the lower animals. Their great annoyance and loss has to be endured. Sometimes when there is much effusion in dependent parts it may be desirable to puncture or lance the skin in a few places and allow the effusion to escape, and prevent suppuration.

At first, soft and restricted diet is to be prescribed along with the physic. After that good feeding is required.

Some diseases have been thoroughly exploited; there is little or nothing more to be found out regarding them. Specific drugs and lines of treatment have been adopted for them. I believe it is not so regarding erysipelas. The medical profession has had long and frequent experience, and tried many things and many ways, but there is yet abundant room for investigation and progress.

DISCUSSION.

Mr. HANNAY said he did not know much about erysipelas in animals unless it was a condition the same as he had seen a few times, and which he had successfully treated with nuclein. He had also used antistreptococcal serum with satisfactory results.

Mr. WILSON (Lanark) said he wished to ask Mr. Cameron how he would distinguish what he termed erysipelas from the lesions caused by the malignant oedema bacillus. He believed he had seen one or two cases which might be called erysipelas.

During this summer he had been called to a horse with a tremendously swollen hind leg; the animal had a very weak pulse and a temperature of 107 F. when he saw it. The owner thought the case an ordinary weed, but the extremely weak state of the horse was distinctly characteristic. In addition there was a lot of milium vesicles over the whole limb and a nasty sticky effusion exuding down the whole of the leg. The leg was extremely painful, and the horse looked like dying. He did not know whether the animal was cured by its inherent spirit or by the treatment he prescribed, namely, salicylate of soda internally, along with whisky or beer, sweet milk and a good oatmeal gruel. He bathed the limb with cold water and an antiseptic. There were no signs of injury to the limb and no sloughing took place.

With regard to cold water treatment, some years ago he had a case of what might have been erysipelas in a bull, which had an infected navel. The skin round the navel was bluish or purple in colour. The owner had bathed the part with hot water, but it had extended and when he saw it the affected part was as large as his hand and dark purple. He stopped the hot water and ordered cold water to be applied for several hours, and

had the part rubbed with turpentine at intervals. A large slough separated. In his opinion the cold water and turpentine had stayed the extension. When there was quickly extending inflammation due to invasion by micro organisms he had frequently tried continuous bathing with cold water and rubbing pure turpentine, and he thought it had had the effect of arresting the spread of the infection better than anything else. In most cases indeed they might as well kill the animal as bathe it with hot water, because the heat of the water seemed to encourage the growth of the micro-organisms. He wished to thank Mr. Cameron for bringing such an interesting paper before them.

Mr. NIXON said that he did not know if he had ever seen erysipelas but he had met cases to which the term might perhaps have been applied. There had usually been some breach of surface about an angular reflection, which ran on to supuration.

Mr. GREIG hoped it would not be considered presumptuous on the part of a student to speak. He was impressed with the fact that erysipelas seemed to be more rare than he had suspected. He had been interested to hear Mr. Storie express his doubt about having ever seen a case of erysipelas in our animals. Curiously enough he had the pleasure of acting as locum for Mr. Storie last year, and during that time he considered he had a case of erysipelas. He would try to describe it.

The patient was a heifer and the owner stated that for two or three days he had noticed her out of sorts, dull and depressed, and off her food. That was all the information he got. He found the heifer down with prostration, and an extensive swelling over the right quarter. The skin was hard and tense with a cold clammy feeling, and the tail was quite dead. The limits of the swelling were quite well defined. At the time he did not know what it was, but since entering his final year he had put it down as erysipelas. The animal was obviously in pain, and he simply gave it a sedative and warned the owner the case was hopeless. It died that night.

The CHAIRMAN said he wished first to thank Mr. Cameron heartily for bringing forward the excellent paper on erysipelas which he was sure had at least stimulated their faculties of thinking. From the discussion it appeared that the disease was not regarded among veterinary surgeons as a very common condition. He had not met with many cases of what he would call erysipelas, and any cases he had named as such had been of a phlegmonous character. His cases had been for the most part in horses and strange to say had nearly always been in the hind legs, beginning frequently about the coronet, in some cases higher up the leg. Another peculiar feature was that his cases had been mostly among horses belonging to coal merchants or contractors, and consequently horses going about very dirty places and with the skin and hair about the legs naturally very much soiled. These cases began from injury, possibly, but difficult to ascertain, because by the time he got them there was considerable swelling. One could notice, however, if one got them early enough that there were some bullae on the skin. It ran its course very rapidly and there was soon sloughing of a portion of skin. There was constitutional disturbance and great pain to the animal, which was very lame and evidently much distressed.

Mr. Cameron had remarked that some of the authorities stated that erysipelas was very common among dogs. He had considerable experience in dog practice, but he could not recollect anything of that nature. He believed erysipelas occurred in animals, and perhaps oftener than they thought. One thing that might keep them from diagnosing the condition was that their patients were covered with a large amount of hair, and they had not the same opportunities as medical men with human beings. In the cases he had described as erysipelas, the

treatment he adopted was that he generally gave the animal a ball containing aloes, calomel, and nux vomica. He was in the habit of clipping the hair round the part and smearing all round the edges of the inflammatory site with glycerine and belladonna. He also used an antiseptic poultice or dressing to hasten the separation of the slough. Lately he had been using ichthyol in the form of an ointment. He also administered quinine with iron and stimulants, and if necessary gave a sedative, as there was great pain when sloughing was taking place. With horses he found it advisable to place them in slings, but if big loose boxes were available they would generally lie down.

He was sorry to note one remark in Mr. Cameron's paper that serum treatment had been tried in human practice, but had not given good results. He had not been able to read up the subject from the human standpoint, and was not able to say much about it. It was supposed that erysipelas was due to the streptococcus pyogenes, and it was not known why these organisms should be in one case quite harmless and in another make the skin inflamed. He had hoped that good results might have been obtained from antistreptococcal serum. The paper was one which would stimulate their observations.

Mr. STORIE said he wished to add a single word. He hoped that Mr. Cameron did not think he had been pouring cold water on the paper when he remarked that he could not say positively that he had ever seen a case in animals. He was doubtful if they ever met with such cases in animals. Reference had been made to cases where the animals were dirty, but in human cases erysipelas was found amongst the better classes, and where there was an absence of dirt.

Mr. HENDERSON thanked Mr. Cameron for his paper. The subject had been somewhat obscure and he could not appreciate the difference between erysipelas and cellulitis. If erysipelas were contagious and occurred in veterinary practice he thought they would meet with groups of it. With regard to the disease spreading by means of abrasions, he had personal experience of erysipelas and could say that abrasions were not necessary to contract the disease. He had seen cellulitis which seemed to resemble erysipelas very much.

Prof. WILSON said he knew little about the disease from a practical point of view, and could not honestly say he had come across a case of erysipelas amongst their patients. Some years ago he had several cases of mammitis accompanied by a good deal of edema and much reddening of the skin. The temperature was not unusually high, and there was no excessive heat about the part; altogether he came to the conclusion that the condition was not erysipelas. He had met with several cases similar to those which had been described, but he did not think he was justified in calling them erysipelas. When one read up the disease in the human subject and compared it with the disease in animals they would perceive there were differences. With regard to the point in the paper dealing with the application of iodine, he noted that the painting of a ring of strong iodine round the margin of the region was considered to be excellent treatment in the human subject. It prevented spreading.

Mr. CAMERON, in reply, said he was not sure he had many comments to make. Mr. Storie stated he had not met with any cases of erysipelas; that was not because he had little or no experience. He knew quite well, however, that there was such a thing as erysipelas. Cases were not always diagnosed with certainty, and frequently they had a crop of similar cases. He remembered at one time having a large number of cases of scirrhus os uteri, but until the beginning of this year he had not had a single case since that time. Regarding malignant edema, he had not had much experience, but one occasion he remembered; two or three horses died

from it, and a number of sheep on the same place were also supposed to have succumbed to it. He thought the word malignant was well employed there, but though erysipelas developed very rapidly it was nothing like that disease.

He thought external treatment with turpentine deserved greater attention than it received. He rarely applied it externally himself, but he believed strongly in giving turpentine along with linseed oil. In preparing his paper he had not had the advantage of references to medical literature such as might be obtained in Edinburgh. He had, however, consulted one recent medical text-book and was surprised to find from it how little progress the medical profession had made in their treatment.

He had had cases which he was quite sure were erysipelas, but he had not had as many cases in cattle as in horses. Besides his experience of erysipelas in horses he had had plenty of trouble with the disease in human kind, and much of it in his own family. He thanked them very much for their remarks on his paper.

On the motion of the Secretary, Mr. Cameron was heartily thanked for his paper.

Mr. STORIE moved a vote of thanks to the Chairman, and the meeting adjourned.

SOUTH DURHAM AND NORTH YORKSHIRE VETERINARY MEDICAL ASSOCIATION

A meeting was held in the Imperial Hotel, Darlington, on Friday, December 1st. The President, Mr. W. Awde, Stockton-on-Tees, presiding. There were also present Messrs. P. Snaith, A. C. Forbes, Bishop Auckland; J. M. Walker, West Hartlepool; H. Peele, Durham; G. R. Dudgeon, Sunderland; W. N. Dobbing, C. G. Hill, and J. H. Taylor, Darlington.

The minutes of the previous meeting were taken as read and confirmed on the proposition of Mr. Hill, seconded by Mr. Peele.

CLINICAL CASES.

"TWIST."

Mr. HILL. Since the last meeting of the Association he had had four cases of twist in the bowels in horses, and the symptoms presented in three of them gave him little idea of what really was wrong with his patients. One brought to his infirmary was practically dying when it came in, and died within an hour. It had no pulse, and medicine had no effect. The other three cases showed little or no pain to speak of, and beyond being dull and drowsy there was little to see, and nothing abnormal could be felt per rectum, and there was little alteration in the pulse. One lived twenty-four hours, another about three, and the third about six hours. Two of the animals were tympanitic, and two tucked up. On post-mortem there was a twist of the colon in each case.

NUCLEIN.

Mr. PEELE asked if any of the members had used Nuclein in pneumonia. He had used it with excellent results. In his experience you were apt to get an abscess at the seat of injection, in spite of all aseptic precautions. He usually gave it alone without the administration of other medicines.

Mr. HILL stated that he had used Nuclein in navel-ill in foals with excellent results. In one case he had used it upon the foal, had abscesses and an open urachus, and had to be lifted up. It did very well, making a good recovery.

He had also used it in distemper in dogs, and in follicular mange in a dog, which was a very bad case, the

dog being very weak, and at first looked as if it ought to be destroyed. After treatment, however, the dog commenced to eat and improve, and eventually did well. He had not had the same experience as Mr. Peele as regards the abscess formation at the seat of injection.

Mr. FORBES had used Nuclein in pneumonia, and in his experience it was invaluable in reducing temperature, one dose usually bringing the temperature down, which lasted for two days.

Mr. WALKER had used Nuclein in the saline solution, but could not agree that it brought down the temperature as described by Mr. Forbes. He once treated a heifer, which had a temperature of 102° for a fortnight, with Nuclein, but the temperature remained stationary all the time, although after commencing to use it the heifer started to feed much better.

He had recently been treating a sow with a litter of six or seven pigs all affected with mange, but the peculiar part of the thing was that some pigs who were being fed for the butcher did not get the disease, although they came in contact with the others. There was no doubt about it being mange, for he found the parasite causing the disease in large numbers.

FARMERS AND SURGICAL INSTRUMENTS.

Mr. SNAITH read a letter he had had from one of his clients, as follows:—

Dear Mr. Snaith,—I have for some time thought of having a milk fever syringe, and on looking through Arnold's catalogue I fixed on having what they call the "Adaptable." After I got it I experimented on it with two basins and could not satisfy myself in the working of it, and could not be sure whether it was intended to inject air or liquid, so I wrote them for some enlightenment, and in their letter they said it was intended for to inject liquid, but if I wished to inject air they would exchange it for me. What would you recommend me to do? Up to now I have never known us have a cow with milk fever, but I thought one might be useful at some time. I hope you don't think I am asking too much of you. Yours truly, —

Many of the members expressed the view that they thought it was most undesirable to sell this class of instrument to farmers, and that the sale of such like instruments should be restricted to veterinary surgeons.

Mr. SNAITH said that in some instances Arnold's charged less for their goods to farmers at shows when compared with their list prices, and certainly he thought that if anybody was to be let lightly off as regards price it might be the veterinary surgeon.

The view was expressed that the matter might be mentioned to Arnold's traveller when he called for orders.

Mr. DUDGEON proposed, and Mr. Walker seconded, that beyond mentioning the matter to the traveller no action be taken, as without a doubt Arnold's—and other firms—would continue having their stands at shows, and sell their goods to anybody who paid for them.

UNEXPLAINED SYMPTOMS—DEATH.

Mr. SNAITH. On reaching the farm he found two heifers laid down, frothing at the mouth, jaws rigid and their limbs stuck straight out, like a wooden animal, pulse and temperature were normal, the head was drawn right back towards the middle of the back. There were no nervous symptoms present, the animals being perfectly quiet, and could eat and chew their cud. One heifer had been given a draught for inflammation down the nose just before he got to the farm, and soon afterwards the jaws relaxed, he got it on its legs, and it walked about half a mile to the farm. The other heifer got a dose of medicine down its nostrils, the jaws relaxed in this case. He treated the cases with sedatives, and both got a dose of opening medicine. One heifer

lived for three weeks, and the other five and a half weeks. He made a post-mortem, but there was nothing to see to account for the symptoms. There was some grit in the second stomach and splinters of solder. The disease was not tetanus, although certainly like it in some respects, nor lead poisoning, nor due to lightning. It looked as if the animals had eaten some poison, which had become absorbed into the system.

He was at a loss to account for the mischief, so wrote to Sir John McFadyean, who replied that he could not account for the illness.

Mr. DUDGEON said that the symptoms certainly pointed to some affection of the cerebro-spinal system, and probably the absorption of a poison was the cause.

Mr. HILL stated that he had recently had a case of acorn poisoning in a bullock, and on making a post-mortem he found that the 4th stomach and bowels were deeply congested, these symptoms being rather different to the symptoms of acorn poisoning as described in *The Veterinary Record* lately.

R.S.I. CONGRESS—DELEGATE.

A communication was read from the Royal Sanitary Institute inviting the Association to send delegates to the Congress to be held at York from July 29th to August 3rd, 1912.

Mr. DUDGEON proposed that the Association be represented at the Congress, and Mr. Hill seconded.

Mr. DUDGEON proposed, and Mr. Walker seconded, that Mr. Awde represent the Association at the Congress, and this was carried unanimously.

CONTROL OF TUBERCULOSIS.

A communication was read from the Association of Veterinary Officers of Health which contained a scheme formulated by Mr. Lindsay, solicitor and Town-Clerk Depute, Glasgow, which, in his opinion, was necessary in order to get uniformity and to place the milk supply under satisfactory supervision and control.

The communication also contained a resolution which was unanimously adopted at the annual meeting of the Association held in Edinburgh on October 13th last, which resolution was as follows:—

"The delegates and members assembled at the annual meeting of the Association of Veterinary Officers of Health held at Edinburgh on 13th October, 1911, recognising the danger to the public owing to the prevalence of tuberculosis amongst animals, and particularly by the consumption of the meat and milk of such animals, respectfully and urgently call upon the Government to take immediate steps to control the disease by—

(1) Scheduling tuberculosis as a contagious disease under the Diseases of Animals Act, with partial compensation for all tuberculous animals and carcasses notified and condemned, payable out of State funds for a limited period.

(2) Offering financial assistance to all owners and breeders of stock who are willing to take the necessary action to breed tubercle-free herds.

(3) Compelling owners of property to provide sanitary buildings in which to house healthy animals, by means of State loans if necessary—the occupants of such buildings to keep them in a cleanly condition.

(4) Taking such further action as may be considered necessary in the future to completely eradicate tuberculosis from the midst of farm animals: and

(5) Placing under adequate control sea-borne supplies of meat and milk."

Mr. DUDGEON thought that there was much food for thought in the communication which had been read, that there was enough to occupy one meeting in discussing it.

The general opinion was expressed that the members were entirely in sympathy with the scheme formulated by Mr. Lindsay, and the resolution was adopted by the

meeting: it was proposed by Mr. Snaith, seconded by Mr. Peele, and carried unanimously, that the Secretary write to the Secretary of the Association of Veterinary Officers of Health and inform him that the Association were in sympathy with his letter.

Mr. AWDE stated that an omission occurred at the last meeting, as he understood that owing to an oversight Mr. Dudgeon had not received the thanks of the Association for his services during his year as President. He had now very great pleasure in proposing that the best thanks of the Association be given to Mr. Dudgeon for his conduct in the chair. This was seconded by Mr. Walker, and carried unanimously.

Mr. DUDGEON suitably returned thanks.

PRESIDENTIAL ADDRESS.

Mr. W. AWDE, F.R.C.V.S.

Gentlemen,—I very much appreciate the honour you have conferred upon me in electing me the President of this Association for the ensuing year. It is not the first time I have occupied that position, but that will not lessen my responsibility; it will only I hope stimulate me to try and make the position of the Association more secure than it now is, so that when my year of office is ended it will be better numerically and financially than at present. In order to do this I shall require the co-operation of all our members by their attendance at meetings, providing papers for discussion, and by inducing other members of the profession to join the Association. Being one of its first members I am not satisfied with its progress so far as numbers are concerned. We have had quite a large membership since it began, but unfortunately from numerous causes the number of resignations have generally kept pace with the election of members, and as a result the numbers have remained stationary. It has often been said, and with truth that there is a lack of cohesion amongst members of the veterinary profession. When we look about us, what do we find? There are more than half of the profession who are not members of any veterinary medical association, and some of those who are, hardly ever attend a meeting, and seem to have lost interest, except in their own concerns. They evidently have forgotten the motto of their profession, *Vix unita fortior*, and do not live up to its teaching. It is therefore no wonder that the veterinary surgeon who does not mix with his brother practitioners regards them with distrust and suspicion, and often forgets that he has any duty to perform either to his neighbour or to his profession. Attendance at meetings not only tends to the diffusion of knowledge, it often affords opportunities for the discussion of difficult or obscure cases, but it also assists in rubbing off one's corners, and in seeing our neighbours and coming into closer contact with them and getting to know them better and to find that they are not such bad fellows after all, and quite different to what we expected. We have had many lessons during the present year as to what combination can do by what has occurred in the labour world, and if only the profession would stick more closely together they would be able to improve their position, and we should not hear so much about cutting prices.

As a result of the action of the teaching staff of the Royal Dick Veterinary College and the National Veterinary Association, the way has been opened for the amalgamation of the Veterinary Societies with the National, and a scheme evolved by which the members of the Societies can be affiliated with the larger one on payment of so much per head. This matter has been brought before you for consideration, and so far as I can see there are great possibilities in the scheme, and if carried into effect it will be possible at any time to ascertain the feelings of the profession, and to give voice to them. I only hope that it will induce more members

of the profession to join the local Veterinary Medical Associations.

The introduction of motor cars and motor vehicles of all kinds have displaced horses to a very large extent in towns and has made a considerable difference to the revenue of town practitioners. It is to be hoped that the findings of the Royal Commission on Tuberculosis will yet open the way to more examinations of cows' udders by practitioners, particularly in the country districts, as the insanitary conditions under which they are kept in the winter time are well known. It is a pity that Mr. Burns' Tuberculosis Bill was abandoned.

Whole time appointments to County Councils and municipal bodies are certainly on the increase, although one could wish they were more numerous. Municipal bodies have now quite an army of officials of various kinds to look after the health of individuals. Health visitors to go into their houses and instruct the mothers as to feeding their children with milk, etc., but it seems to me that the source from which the milk is obtained should be first put right, or all the other instruction will be thrown away, and disease disseminated.

Lately we have seen cases recorded of medical officers of health paying visits to inspect milk cows in byres for themselves. We as a profession ought to protest against such a course unless he be accompanied by a veterinary surgeon to advise as to the condition of the animals.

I am sorry to have to record another outbreak of foot-and-mouth disease within the last few days at Bridgewater, Somerset. No doubt in the hands of the Veterinary Advisers of the Board of Agriculture the disease will soon be stamped out. These outbreaks have been rather too frequent of late, and so far as I have been able to find out, the cause of the outbreaks has not been satisfactorily solved.

Anthrax seems to be very much on the increase, and several outbreaks have recently occurred amongst Army horses.

I much regret the scrappy nature of my address but hope for a successful year for the Association.

Mr. DUDGEON proposed a vote of thanks to the President for his address, and this was seconded by Mr. Peele and carried unanimously.

Mr. AWDE returned thanks, and hoped that the members would try and attend the meetings, and bring forward subjects for discussion.

THE COAL MINES BILL.

Mr. PEELE said that he had a statement with reference to the Coal Mines Bill which he would like to bring before the Association, as he considered that it was most important. If he had had time he would have called a meeting of the members, but it was only about a week ago that he was acquainted with the matter, and as the report stage of the Bill might take place any day, it was necessary to act promptly in the matter. About a week ago, said Mr. Peele, a colliery manager called his attention to Clause 109 (3) in the Bill.

[These Clauses of the Amended Bill, with the reception of the deputation, appeared in last week's issue, p. 352; and the passing of the Bill with an Amendment to Schedule III. (1), at p. 366.]

After his conversation with the colliery manager he saw Mr. Elphick, of Newcastle, and wrote to the Secretary of the Royal College of Veterinary Surgeons, who replied that the portions of the Bill which Mr. Peele called his attention to were not in the original Bill which he had seen, but were inserted in the amended Bill which had come into his office during his absence on holiday last August, and thus had escaped his notice. Mr. Peele then got into communication with Mr. Thatcher, the solicitor of the College, and matters were pushed forward.

Mr. Peele said the person to apply the test ought be none other than a veterinary surgeon, for a horsekeeper might be considered by some people to be a competent person, but he was certainly not the proper person. A veterinary surgeon might be a competent person enough to vaccinate a child, but he was not a proper person, that person of course being a medical practitioner.

Much surprise was expressed by the members that it had been left to individual members of the profession to do the initiative in the matter, and it was felt that matters ought not to have been allowed to have gone as far as they had done without the Royal College of Veterinary Surgeons taking prompt action. Somebody was certainly to blame, and it looked as if the Secretary of the College ought to have called the attention of the Parliamentary Committee to the parts of the Bill relating to animals.

It was felt that the thanks not only of the Association, but also of the profession as a whole, were due to Mr. Peele for the action he had taken in the matter.

After some further discussion the following resolution moved by Mr. Peele, and seconded by Mr. Snaith, was unanimously carried:

"That this meeting of veterinary surgeons having considered the clauses relating to the animals of the mine in the Coal Mines Bill are of the opinion:

1. That the special Inspectors to be appointed by the Secretary of State for the inspection of horses and ponies, and reporting on their management and treatment should be veterinary surgeons, in view of the special qualifications held by them.

2. That the first paragraph of Schedule 3 of the Bill should be so worded that it would be impossible for any other person than a veterinary surgeon to apply the prescribed test, and to certify any animal to be free from glanders.

It was also resolved to send a copy of this resolution to the solicitor of the Royal College of Veterinary Surgeons, to be forwarded to the Right Hon. Hy. Masterman, Secretary of State, without delay, and that each member of the Association send a copy to the Member of Parliament representing his constituency.

The members afterwards had tea together at the Hotel.

JAMES H. TAYLOR, Hon. Sec.

LIVERPOOL UNIVERSITY VETERINARY MEDICAL SOCIETY.

A general meeting was held at the University on Tuesday, December 5th, at 3.30. Present: Jno. Share-Jones, Esq., President, in the chair; Messrs. J. Sumner, H. Sumner, J. B. Wolstenholme, E. Wood, Thos. Dobie, W. J. Fletcher, G. H. Locke, Frank Jones, F. A. Ball, F. S. Warburton, J. Maguire, T. G. Duggle, A. Walker, H. Holroyd, A. W. Noel Pillers, D. C. Matheson, A. B. Mattinson, T. Eaton Jones, W. Woods, and A. Richardson.

Apologies for non-attendance were received from Messrs. R. Hughes, A. Taylor, E. Faulkner, H. J. Hewetson, D. M. Storrar, and J. P. Heyes.

Mr. J. W. BRITTLEBANK, of Manchester, was proposed for membership on the proposition of Mr. G. H. Locke, seconded by Mr. J. B. Wolstenholme.

On the motion of the President, it was unanimously agreed to send a letter of sympathy to Mr. W. A. Taylor expressing the sincere hope that he will be speedily restored to health.

The PRESIDENT reported that the mare upon which the operation of ovariectomy had been performed prior to the last meeting was on view.

PATHOLOGICAL SPECIMENS.

NOTES BY MR. D. C. MATHESON.

1. *Fibro-Adenoma—Mamma.* Two bitches, showing the type commonly met with in the posterior mammae of old bitches. Both were cystic and undergoing processes of ossification.

2. *Lipoma in the Mesentery.* The chief interest in this case was the fact that the growth had caused strangulation of a portion of the rectum.

[Mr. J. B. Wolstenholme.]

3. *Septic Arthritis and Ostitis in a Dog.* The enlargement of the carpus came on somewhat suddenly, and continued to increase in size for a month. The dog had previously had a similar swelling in the hind legs, but that had gradually disappeared. There was no skin wound.

On opening the enlargement pus escaped freely, and upon dissection it was found that the distal extremity of the radius and ulna were extensively affected with ostitis and periostitis.

[Mr. W. J. Fletcher.]

4. *Tuberculosis* affecting the vertebrae of a pig.

5. *Sarcoma.* Bitch. Unusually large, completely surrounding one kidney, which, however, was intact.

[Mr. T. S. Atkinson.]

6, 7, 8. *Psammoma.* These were of the usual type, commonly termed Psammomata in veterinary pathology—they differ from tumours so described in human pathology. On this account it has been suggested that they might be termed Cholesteomata. This term, however, closely resembles that appropriated by another type of growth occasionally met with in human pathology, but rarely encountered in the lower animals. The close resemblance of the two terms, as pointed out by Mr. Fadyean, would perhaps tend to confusion if the first were adopted.

[Mr. S. Jackson, Mr. A. Richardson.]

PSAMMOMA.

Mr. J. B. WOLSTENHOLME. A brown cart mare, 10 to 12 years old, was bought from an unknown dealer at the end of September, and examined after purchase, it was reported as "worn and a shiverer." Admitted to hospital on October 3rd, reeling, and had very little control of the limbs. Pulse 72, temperature 101. The symptoms suggested cerebral trouble, possibly due to over feeding, as "feeding well" had been reported.

A dose of physic was given, the stomach and bowels were relieved, the mare seemed well, and went out of hospital for work on October 6th.

After this it was stated that the mare dragged the load along in an aimless, semi-staggering, wandering condition, with head low down to the ground. She would fall down without warning. She fell at work on the 21st October. On the morning of the 22nd she was found on the floor of the stall and could not rise; pulse and temperature practically normal. Was got up with slings, but couldn't stand, laid in the slings with head to the floor. No paralysis. Became violent at times; had to lower to the ground and secure the legs.

Died at 5 a.m. October 23rd. On exposing brain the vessels were seen to be congested, and a considerable quantity of straw-coloured clear serous fluid gradually ran to the ground.

9. *Carcinoma Mamma.* Male dog, a somewhat uncommon condition.

[Mr. A. Richardson.]

10. *Fibro-Lipoma.* Abdomen, pig.

[Mr. E. Burdred.]

11. *Esophagus Cow.* Showing extensive thickening throughout, but no indications of malignant disease.

[Mr. Edwards, Mold.]

12. *Epithelioma of Stomach, Horse.* A specimen of interest on account of the comparative rarity of gastric cancer in the lower animals. The growth was a squamous celled epithelioma, originating in connection

with the left sac of the stomach; the growth was of a large size and had invaded the right sac.

13. *Epithelioma.* Bowel, horse. A cylindrical celled tubular epithelioma the size of a child's head, and obstructing the lumen of the bowel. Two small growths of an identical histology were present in the substance of the liver.

[Mr. H. Sumner.]

DISEASE OF SUSPENSORY LIGAMENT:

CHRONIC INFLAMMATION.

Mr. J. MAGUIRE. Carriage horse 16-2, 4½ years, had been put to work at 3½ years. At 4½ years showed symptoms of lameness. After returning from work he would raise one hind leg and keep it suspended for a few minutes, then place it on the ground again: a little while after the same would be done with the other leg.

While standing he would put the weight of the hind quarters on the toes, the pasterns would be bent back and down, the hocks nearly straight, as it were fully stretched, the pelvis raised, giving the appearance to the hind quarters of being some two or three inches higher than the fore quarters; the fore limbs were set back under the chest.

The symptoms were more or less aggravated according to the amount of work done. A peculiar feature was the horse constantly assumed a lying posture, rarely standing up. On returning one day he lay down and continued to do so for a fortnight except for short intervals of feeding. At this stage he showed all the symptoms of an acute shiverer. There was also a swelling at the seat of curb. Otherwise there were not any positive indications of disease.

Gradually these symptoms subsided and the animal was apparently progressing favourably when an attack of congestion of the lungs finished his career. The ligament was twice the normal thickness and rounded on section.

15. *Osteoma.* Jaw of a horse, originating in the neighbourhood of the second molar. (Mr. J. P. Heyes).

16. *Carcinoma.* Testes in dog in size three times the normal, lobulated externally. The other testicle had undergone atrophy and was about the size of a horse bean.

(Mr. P. Carter).

17. *Melanoma of lip.* Red cow.

18. *Tuberculosis of the liver.* Fowl.

GASTRITIS AND INTUSSUSCEPTION.

Mr. RICHARDSON. The horse from which this specimen had been removed had been in perfect health apparently up to within three weeks of the time of its death.

It was an aged Clydesdale gelding—when first reported out of health the symptoms shown were those of defective vision and change of manner—was apparently stubborn and awkward, and responded slowly to the word and sound, as the carter said, "wrong in his head." When being led he had a peculiar boring movement, and was conducted through ordinary traffic with difficulty.

Upon examination there were no local indications of eye disorder, and the constitutional symptoms were negative. The nerve symptoms became more pronounced and three days prior to death they became more violent in character. The restlessness, elevation of the head, excitement, and increased difficulty of control, together with stumbling when moved were the chief symptoms. Ultimately he got down and was unable to rise, and died of exhaustion.

Two specimens of cases of gastritis in the dog were shown, each showing a condition not frequently reported—that of eversion of the duodenum into the stomach. Some inches of the duodenum being everted and in one case there was also intussusception.

Referring to the specimens of psammoma the President observed that the cases reminded him of a brain which was handed to him for dissection some time ago. It was taken from an animal, a patient of Mr. James Sumner which had developed symptoms similar to those described in these cases. Psammoma had been suspected, but no tumour had been found in the ventricle, so the brain was sent to him for dissection. During dissection he (the President) found a number of very small gritty bodies along the edges of the velum interpositum. The bodies were of a yellowish colour, and a microscopic examination showed that they consisted of or contained crystals of cholesterol, which were a characteristic constituent of psammoma. He had never seen cases of this kind reported, and he would like to hear from Mr. Matheson or Mr. Wolstenholme whether they had encountered the condition.

Both these gentlemen replied to the effect that they had not observed the condition.

At the conclusion of the pathological demonstration a vote of thanks was accorded to Mr. Matheson.

SOME OBSERVATIONS ON BOVINE TUBERCULOSIS AND A PURE MILK BILL.

By A. B. MATTINSON, F.R.C.V.S.

The subject of bovine tuberculosis and its eradication is one of paramount consideration to the stockowner and the whole of the agricultural industry; various suggestions and schemes have from time to time been put forward, but as yet the State, in the United Kingdom, have not considered the subject of sufficient importance to introduce any legislation, with the exception of the Tuberculosis Order of the Board of Agriculture of 1909.

Various reasons may be advanced for this apparent indifference, amongst which the following are probably the chief ones:

1. The ubiquity of the disease, which makes the problem appear too big to be tackled.
2. The probable cost of eradication.
3. The objection of unintelligent stockowners, who do not appreciate the insidious nature of the disease, and who object to all restrictions.
4. The absence of sufficient political power to force the hands of a Government.
5. The belief that it may be got under subjection by private enterprise alone without State aid.
6. The common belief in the unreliability of the tuberculin test.
7. The question as to whether the end would justify the means.

Before going into these objections to a scheme of eradication, it may here be advisable to recall the agitation of the Federation of Butchers Association in 1908 for a warranty as to soundness of cattle bought by them for slaughter, which in this case really amounted to a warranty of freedom from tuberculosis, and which at the time raised the question into great prominence amongst Butchers' and Farmers' Associations. The butchers demanded this warranty to avoid all trade losses, and the farmers with equal unanimity refused to give it, and insisted upon the State paying for all losses for meat "cut down."

To a disinterested party the attitude of either—to expect that one should alone bear the losses of the other—seems equally illogical; and compensation by the State is equally out of the question. No Government can reasonably be expected to provide funds merely to indemnify an individual or trade against monetary loss unless the State is to be the gainer; if public money were to be spent otherwise in a case of this nature it would simply amount to paying an individual that he should abstain from foisting a noxious article upon the

public, and this can already be prevented by the Public Health, and Foods and Drugs Adulteration Acts. Compensation under the Diseases of Animals Acts was never intended to indemnify an individual against trade losses, but is essentially, where the Acts are administered in a wise and sympathetic spirit, a payment to reward an individual who assists the State in the permanent suppression of a cause of national loss.

There cannot be two opinions amongst those acquainted with the subject regarding the great losses to agriculture annually from the scourge of tuberculosis, and the opinion that it can be controlled is undoubtedly gaining ground. The majority of advocates of leaving this question to the individual are those who have no pecuniary interest in agriculture, and no material knowledge of the live stock industry of the country. The Tuberculosis Order of the Board of Agriculture and Fisheries of 1909 makes it evident that that body appreciates the necessity and wisdom of tackling this question, but party exigencies in the House of Commons have necessitated that the Milk and Dairies Bill of 1910, upon which the above mentioned Order depended for its existence, be left in the background.

That the Tuberculosis Order should have depended upon the Milk Bill was to be greatly regretted. The question of bovine tuberculosis is big enough and important enough to have merited a Bill of its own, and it is to be hoped that it will eventually be approached directly by the Board of Agriculture, and not merely receive cursory treatment at the hands of lay inspectors of the Local Government Board. I may here say that I regard as laymen all inspectors of meat, dairy, cattle, and cowsheds who are not veterinary surgeons, with the exception of a few gentlemen highly qualified in such work and well known to all of us.

The only comprehensive and economical system of dealing with bovine tuberculosis necessitates that the whole of the administration should be in the hands of one body, and that body should be the Board of Agriculture. The eradication of tuberculosis is not to be regarded as a subject alone: it cannot reasonably be separated from its corollary—the inspection of meat intended for human food, and the officers who are supervising the one are the only ones to see to all, for each is complementary to, and intimately associated with, the other. Where a dual system of inspection by the officers of the Board of Agriculture and the Local Government Board goes on, differences must occur: the Medical Officer of Health will not allow his preserves to be encroached upon by the Veterinary Officer, and it is the duty of the latter to return the compliment. If either interferes with the work and duties of the other friction must ensue, and efficiency will suffer, this entails a waste of public money in all cases, and also reflects adversely on the results obtained by any measure. All measures affecting directly the health and usefulness of live stock should undoubtedly be controlled solely by the Board of Agriculture, and the appended scheme is founded on such a system, which can only be obtained by complete harmony and co-ordination between the Agriculture Associations, Veterinary Schools, County Councils, and the Board of Agriculture; all working for the benefit of the agricultural and live-stock industries, the welfare of which is of national importance.

That there should be an almost perpetual and acrimonious warfare of words between the veterinarian and the Medical Officer of Health as to whom is the greater authority on dairies, meat, etc., is greatly to be regretted, and wholly unnecessary if each will stick to his legitimate offices. We have it on great and ancient authority that "the tongue is an unruly member," and on that account this controversy has from time to time degenerated to a very low degree: the only efficient safeguard against personal and professional enmities and differences is for each department of Government

to jealously safeguard the interests of the class whose welfare it has charge of, but at the same time for all to loyally assist each other in matters pertaining to the public weal. I have a profound respect for the Medical Officer of Health, and the invaluable services which he renders to the community, but one cannot allow him to assume professional control because he belongs to the senior service: such an argument would be equally reasonable (and equally foolish) if applied by a Naval officer desiring to lead a cavalry charge, by a Chief Constable to a Borough Surveyor, or even by a Town Clerk to a Medical officer of Health.

No legislation on the subject will satisfy all parties, on the contrary it would most likely be stoutly opposed or else killed by apathy unless the press should take the matter up more fully: this would be a questionable gain, as it would probably spread a popular misconception that the dairy farmer and cowkeeper were responsible for the spread of most, if not all, of the diseases which human flesh is heir to.

It is important that any measure for the eradication of Tuberculosis should be as free as possible from harassing and vexatious regulations which would seriously affect the live stock industry, but at the same time it must be sufficiently systematic and restrictive to ensure the control of this scourge.

Any such scheme would necessitate eventually the provision of Public Abattoirs and the efficient inspection of meat, instead of the chaotic, spasmodic, and practically futile efforts of a multitude of lay inspectors of local authorities, whose territories have not the area or rateable value to enable them to pay a properly qualified person to perform these duties. Such a system of inspection would benefit the farmer, for it would enable him to command a higher price for his products, help to resuscitate the home meat trade, and command the attention of the consumer to the benefit of purchasing home grown produce which is practically guaranteed to be pure and wholesome by the local authorities. Although all classes, and most particularly agriculturists are averse to governmental restrictions (the latter most particularly so) it seems probable that the thanks of the coming generation of farmers and stockowners will be freely given to the Imperial and local authorities who extend their sphere of usefulness to dealing in a systematic and organised manner with this and other subjects of prime importance to agriculture which are at present partially or wholly neglected.

Proceeding to deal with the objections to legislation for the eradication of Bovine Tuberculosis, the arguments previously set forth are as follows:—

I. The ubiquity of the disease. This is certainly one of the strongest reasons and it is impossible to have any pecuniary interest in Live Stock without becoming painfully aware of it. Figures of all sorts have been given to show its prevalence, but in a paper of this kind it is not advisable to enter into them, as the accuracy of all is problematical and in a time honoured phrase, "Statistics may be made to prove anything." The moral aspect of this objection, is however the best answer to it, and the fact that a great evil is exceedingly prevalent and very widespread, is all the more reason why the State should make a determined and continuous effort to cope with it.

II. The cost of eradication. This, like the previous objection has been backed up by figures which befog all but the individual who elaborated them, and although it would be folly to embark upon such a great undertaking without regard to the annual and ultimate cost, it would be better for the officials of the Board of Agriculture to prepare some disinterested statistics giving an approximate idea of the prevalence of the disease in the various counties, and this can only be done with any degree of accuracy by first scheduling the disease. Tuberculosis should not be classified nor compared with rapidly spreading epidemics, such as Foot and Mouth disease,

Pleuro Pneumonia, &c. It is a disease of comparatively slow progress, and thus lends itself to a policy of clearing one district, or group of districts at once, thereby curtailing expenses of administration and eradication.

III. The objections of Stockowners to legislative restrictions.—These have in the past been largely brought about by the method of administration of the Diseases of Animals Acts, and the objection to having diseases diagnosed by constables, half-pay officers, and other friends of someone in authority. These objections, it is to be hoped, will be removed by an improvement in system, but sad to say this method although sure is exceedingly slow; could the office of President of the Board of Agriculture only be occupied for a few years by an orator who could give full and liberal information on the best manner of growing "rare and refreshing fruits for the parched lips" of the down-trodden clod-hoppers, I believe it would be possible to convert agriculturists very rapidly to the benefit to be gained by reasonable restrictions.

Apart from this, however, the objection of one class must not be allowed to interfere with legislation for the benefit of the majority. Reference to legislation in the last decade gives many instances of how individual and class objections to numerous measures, have, rightly or wrongly, been wholly disregarded by Governments, except where it has been on some matter largely affecting votes.

IV. The absence of sufficient political power to force the hands of a Government.—This is a very important power in the hands of all organised industries. Members of trades unions largely support the claims of each other, and thus they can exert great political pressure upon a party, as well as run numerous Members of Parliament. The Central Chamber of Commerce is opposed to the Principle of running "agricultural" candidates for Parliament, as it is questionable if they could do so successfully, and it is equally doubtful if farmers will ever collectively be able to exert great political force.

V.—The belief that Tuberculosis may be eradicated by private enterprise unassisted by State aid.—It is hardly unreasonable to question the *bona fide* of the advocates of this principle: it may be taken to be founded on apathy, ignorance of the subject, or a desire to shelve it to make way for other measures in which the party or individual has more interest, or which is more likely to appeal to the majority of the electorate.

VI. The common belief in the unreliability of the Tuberculin test. This has been originally quite justifiable, but owing to the great improvement in this and all other biological products and the standardization of the same there is now little reason for it. It is comparatively easy to prove to any intelligent individual that the test when properly applied gives an exceedingly small margin of error. The standardization of Tuberculin, and its issue by the State alone to properly authorised persons is the only method of completely defeating this objection and preventing the fraudulent application of the test.

VII. The question as to whether the end would justify the means. During one of the early sittings of the Royal Commission on Tuberculosis, Sir Thomas Elliott is reported as having said, (with reference to the necessity of legislation for the eradication of Bovine Tuberculosis) that "If it were possible it is not necessary, and if it were necessary it is not possible." At that time the possibility seemed much more remote than at present, but it is difficult to understand the reason for stating that even if possible it was not necessary. One cannot foretell the result of the enactment of even the most mild and unsophisticated looking bill, but I believe that it would be possible to proceed cautiously with this subject, and to show the ultimate advantages of such legislation.

(To be continued).

Another Ringbone Case.

Before Sheriff Napier at Kirkcudbright on Tuesday, November 14th, proof was led in an action by Thomas Black, farmer, Parton Mill, against Hugh Crawford, horse dealer, Cotton Street, Castle-Douglas, tenant of Marchfield Farm, Castle-Douglas, in which pursuer seeks decree for payment of £37 from defender as the price of a three-year-old Clydesdale gelding belonging to him, which was exposed at Mr. Carson's dispensing sale at Diamond's Laggan on 20th May, and bought by defender. The horse was by arrangement kept at Parton Mill for a short time after the sale; and thereafter defender refused to take delivery of it on the ground that it was suffering from ringbone and disconform to warranty. The horse was put up at livery in Castle-Douglas, and ultimately sold by auction under a Sheriff's warrant. It was bought at that sale by a brother of the pursuer for £30 9s., and is now again in possession of pursuer, at Parton Mill.

Mr. W. Nicholson, solicitor, Kirkcudbright, conducted the case for pursuer, and Mr. J. R. Saunders, solicitor, Castle-Douglas, for defender. Mr. Milligan, solicitor, Dalbeattie, watched the case on behalf of Mr. T. Campbell, V.S., Castle-Douglas.

W. Wallet, auctioneer, Castle-Douglas, the first witness, stated that Mr. Black sent a four-year-old filly and a three-year-old gelding to the Diamond's Laggan sale. Both were warranted "quiet and sound as far as known." The filly was passed at £31.

Mr. Saunders, in cross-examining, regarding the subsequent sale under warrant, said: You don't attach much importance to the price that was obtained at the second sale?—No.

You know that is a matter which can be very easily arranged?—I may think what I like, but I don't say so.

By Mr. Nicholson: The second sale was quite a *bona-fide* one. He had heard that Mr. William Johnston, horse dealer, was the last bidder, but that he omitted to take his bid.

Thomas Black, pursuer, deposed that the gelding was bred by himself, the sire being a horse belonging to Mr. Picken, Torrs; he thought "Keir Victor." It was not at all likely that Mr. Picken would keep a horse having hereditary ringbone or likely to produce it. He understood that such horses were generally exported to get rid of them. This gelding had been treated in August of last year for a sprained shoulder, but the lameness caused by that soon disappeared, and there had been no subsequent lameness. Mr. Campbell, V.S., Castle-Douglas, who attended it at that time, "chapped" the feet with a hammer and told him that he was right in the legs and feet. On Wednesday, 24th May, he received a letter from defender, dated the 22nd, in which he said: "I am sorry to inform you that I have been informed that the gelding you presented at Diamond's Laggan sale on Saturday, and which I purchased, is a lame horse, and that you presented him for sale knowing he was a lame horse, and failed to disclose same. Therefore if this be true I refuse to take him." That was the first suggestion he heard from anyone that the horse was suffering from lameness. He did not answer the letter, but Mr. Crawford came to his place on the Saturday afternoon, and they again met in Castle-Douglas on the Monday. Witness thought it was simply a case of rue-bargain with him. He was so confident that the gelding was right that at the meeting in Castle-Douglas he offered to send one of his men down to Marchfield with the horse to have it examined by Mr. Campbell, V.S., on the footing that if it was passed by him it was to be left; if not, it was to be taken back and there would be no more about it. Mr. Crawford agreed, and witness, in pursuance of that agreement, went to Mr. Campbell's office and arranged for

him to examine the horse next day. He told Mr. Campbell that defender was refusing to take delivery because he said it was lame, and that was what he had to find out. Witness did not himself go with the horse, but sent his man, James M'Gaw, and when M'Gaw returned he reported to him that Mr. Campbell, after trotting the horse and examining it, said there was no lameness about the horse. The same afternoon he received a telegram from Mr. Campbell asking him to go to Marchfield at four o'clock for a second examination of the horse. He went to Marchfield, but after waiting for two hours, and Mr. Campbell not coming, he left. The horse came back that night, and along with it was a pencilled note from Mr. Campbell to this effect: "I am very sorry I did not meet you as arranged. Mr. Crawford waited, and the horse was pulled out and trotted. He went very lame on the near fore leg. I did not observe the lameness in the morning, but after the rest he has shown it." In that certificate there was nothing about the horse suffering from ringbone, and he would have expected him to mention that if he had seen such a thing. The horse had been put into the stable during witness's absence from home, and afterwards into a loose box. The loose box had been occupied by calves, and there was dung in it, which covered the horse's hoofs. Next day it was put into the field, and soon afterwards M'Gaw drew his attention to a bruise on the top of one of the hoofs. Witness said he would get to the bottom of the thing, and went and saw Mr. Campbell, who expressed surprise that the horse had developed lameness between the two examinations. Witness asked if he would be surprised to learn that the horse had suffered an injury between the two examinations, to which he replied that he "never jaloused that." Next day witness sent for Mr. George Nicholson, V.S., Kirkcudbright, who examined the horse, and certified that it was going lame from the result of a recent injury.

Mrs. Black gave corroborative evidence on several points.

Thomas James Campbell, V.S., Castle-Douglas, spoke to having paid three visits to Parton Mill in August last, when he treated the gelding for temporary lameness caused by sore shoulder. There would be no malafides on account of that temporary lameness on the part of the seller in representing that the horse was sound in the month of May. It was unusual for a young Clydesdale up to age of three, which had never been worked, to suffer from ringbone. Sometimes ringbone was caused by injury, but in a young animal that had never worked it was generally due to hereditary predisposition. When he examined the horse in August he did not find any ringbone about it. It was for lameness that he was asked by Mr. Black to examine this horse. Mr. Crawford had seen him before that, and also asked him to examine it for lameness. When making his first examination Mr. Kerr, Barnboard, and Mr. Craik, defender's foreman, both suggested that the horse was lame, and witness took the horse out on to the public road to satisfy these men, and they ultimately agreed with him that the horse was not lame. When he left Marchfield, after examining the horse, he went and reported the result to defender, which was that the horse was trotting sound, and that he had passed it. Defender suggested that witness should have lunged the horse—that is, have it run round in a circle—and he replied there was no need to do so for the purpose remitted to him. He agreed to go back in the afternoon to satisfy defender that the examination was correct. It was entirely at defender's request that he went back a second time. He discovered the presence of ringbone at the first examination, but he had not been asked to report on that at all. It was at defender's request that he examined the horse for soundness, and reported that there was ringbone, and that the horse was unsound. He had no previous communication with Professor

McCall before he mentioned the word ringbone. It was after his second examination that it was suggested an accident had occurred between the examinations. He went to Parton Mill and saw the horse again. The injury on the foot might have been sufficient to cause the lameness that was there. The injury to the hoof head, together with the ringbone, would increase the lameness.

Cross-examined: When he instructed the horse to be taken back to Parton Mill he thought he was doing what in the circumstances was right. He did not see any mark on the horse's hoof at the second examination. He saw the horse again on 9th June in the Crown stables, and found it was then going sound. The wound was then healed up.

Mr. George Nicholson, M.R.C.V.S., said he examined the horse on June 3rd, and granted a certificate that a recent injury to the hoof head of the near fore foot was the cause of the lameness which was then present. He did not examine for ringbone, and what he saw would have entirely prevented anyone diagnosing ringbone at that part. It was improbable that ringbone was the cause of the lameness that he saw. On Sunday last he had tested the horse again and found it going sound.

Cross-examined: The cause of the injury might have been a bruise.

James McGaw, ploughman with pursuer, testified that the horse was going sound at the sale and at the first examination. Afterwards he found that both skin and hair had been taken off the foot by an injury.

James Milroy, who had been in pursuer's service for twelve months, corroborated. He never told Mr. Craig, a relative of his, the horse was a lame one. He got a letter from Mr. Saunders, in which it was stated he had said so, and asking him to give evidence for the defence.

John Miller, farmer, Mid-Kelton; Richard Porteous, farmer, Barber's Hall; William Kerr, farmer, Campdouglass; Hugh Parker, farmer, Borland; Francis Burns, dealer, Rhonehouse; and William Brydon, farm manager, Redcroft, spoke to having seen the horse at various periods, and testified that on these occasions it was going sound.

This closed the evidence for the pursuer, and the Court adjourned.

SECOND DAY.—DEFENCE.

Principal McCall, F.R.C.V.S., of the Glasgow Veterinary College, examined by Mr. Saunders, said that on June 9th, at the request of Mr. Campbell, V.S., he examined the horse in question at the Crown Hotel, and granted a certificate to the effect that the horse was going lame in the near fore leg, and with a thickened hoof head, and that the horse was unsound and suffering from ringbone. He could not say how long the ringbone had been there, but thought he would be justified in saying that it had been present for three months and probably longer.

If told that the horse had been treated in August, 1910, for lame shoulder on the same leg, what would that suggest?—It might be the early stages of ringbone. It should not have been difficult to detect either by the eye or hand. In the first stage there was no enlargement. A horse with ringbone was not always lame. In the early stages the horse would be lame, but after the horse had grown there might not be any lameness at all. He saw the mark on the horse's hoof, and concluded that it was a wound healed up. He did not think the wound would cause the lameness. It was simply a skin wound. He believed the lameness arose from ringbone.

Would you be surprised to hear that a certificate had been given that the horse was going sound in the morning and another certificate on the same day that the horse was going lame?—I would be very much surprised

to learn that a horse was going sound in the morning and lame at night with ringbone.

David Craik, foreman to defender, went there on 27th May. He was there when the horse was taken to Marchfield. Mr. Campbell was not present when the horse arrived, and the horse was put in a stable. He saw the horse at a distance being examined. He saw the horse trotted and noticed it was lame. Mr. Kerr was present and asked witness if he noticed that the horse was lame. He saw the horse trotted on the road, and he showed lameness there too. Mr. Campbell asked witness what he would do, and he replied he had got no instructions. He afterwards arranged with Mr. Campbell to take the horse in subject to Mr. Crawford's approval when he arrived. Mr. Campbell said nothing to him about the lameness of the horse, but he was satisfied that the horse was lame, and that was his reason for not wishing to take the horse in. Mr. Campbell came back a second time, and the horse was again brought out. There was no one near the horse that he knew of while it was in the stable at Marchfield. At the second examination the horse was going more lame than in the morning. He saw no mark on the horse before it was sent back. Witness certainly made no mark on it.

Cross-examined—From the time the horse arrived at Marchfield till the arrival of the vet., it was in the stable. He could not say how long Mr. Campbell was at Marchfield. Witness did not remember saying to Mr. Campbell that the horse was lame. He saw the horse trotted on the road, and he said to Mr. Kerr that he thought the horse was going lame. There were no other horses in the stable.

Peter Kerr, farmer, Barnboard, was at Marchfield when the horse was brought out of the stable. He saw it examined by Mr. Campbell. Witness and Craik remarked on the lameness of the horse. He did not hear any remark pass between Campbell and Craik about the lameness of the horse. Witness was satisfied that the horse was lame, and he could not remember having been asked by Campbell if he was satisfied that the horse was going all right. Mr. Campbell said the horse was certainly lame, and witness, on Mr. Campbell's instructions took the horse back to Parton Mill.

Cross-examined: Mr. Campbell examined the horse's hoof-head and said the horse had ringbone. Witness was formerly in defender's service.

Thomas Smith, farmer, Cogarth, which adjoins Parton Mill, said he saw the horse exposed for sale at Diamond's Laggan. In August or September, 1910, Mr. Black told him the horse was lame, and witness went with pursuer to see the horse, and suggested that the lameness was in the pastern joint. The horse had a blister on. He saw the horse for about two months after that, and it was still going lame. He also saw the horse being taken to Marchfield by McGaw, and remarked to McGaw that the horse was a bit lame.

Cross-examined: He had always been friendly to Mr. Black, but he did not think that the pursuer had been friendly to him. The lameness was quite visible to any ordinary observer.

Matthew Dalling, dealer, Castle-Douglas, was in Mr. Campbell's office at Castle-Douglas on a certain day, and he heard pursuer say to defender that the injury he surmised, must have been caused by defender or his man.

Hugh Crawford, the defender, said that the horse was sold at Diamond's Laggan on pursuer's warranty, and the horse was sound as far as he knew. After the sale he asked pursuer to take the horse home and work him for 10 days. He afterwards saw Smith, Cogarth, who in course of conversation said that the horse was a wrong one and would always be so. When witness saw pursuer at Marchfield he said he had not gone there for the horse, but to see him about the truth of the story that he had heard about the horse being a wrong one.

Pursuer said the story was a lie, and that there was some snake in the grass, and that the horse was a sound one. He further said that in order to save talk about the horse being rejected, they might arrange for defender to take the filly instead of the gelding, and give £1 more for it than was offered at the Diamond's Laggan sale, where it had been withdrawn at £31. That arrangement was not carried out. Pursuer offered then to submit the gelding to a V.S. examination, and Mr. Campbell was instructed, but witness's understanding was that the horse was to be examined for soundness and not merely for lameness. Pursuer told him also during the conversation that the story about the horse being a wrong one did not apply to the horse defender had bought, but to the filly. When Mr. Campbell came to report the result of his examination, he said the horse was going sound, but he refused to give defender a certificate of soundness. The horse was never interfered with by defender or his men when in the stable at Marchfield. At the second examination Mr. Campbell said the horse was affected by ringbone. It was Mr. Campbell who sent the horse back to Parton Mill. Mr. Campbell said that the cause of the mark on the horse's hoof might have been caused by the toe of a man's boot. He was in Mr. Campbell's office when Mr. Black came in, and in reply to a question by defender, pursuer said he would not go the length of saying that defender or his men had put the mark on the horse's hoof. It was because Mr. Campbell would not grant a certificate of soundness that he (witness) refused to take the horse back.

Cross-examined: It was not merely the question of lameness that was to be submitted to Mr. Campbell, but the question of soundness. He did not examine the horse on the day of Diamond's Laggan sale. Witness did not see any lameness in the horse at that sale. It was because of Mr. Smith's statement that the horse was a lame one and always would be that he wrote to Mr. Black asking if it was the case that what he heard regarding the horse was true.

Evidence in the action was concluded with the examination of Mr. William Johnston, horse dealer, Dumfries. Mr. Johnston said he saw the horse in dispute sold at Castle-Douglas mart in June, and made a bid for it, but it was knocked down just then, the auctioneer not noticing his bid. A few days afterwards he made arrangements to see the horse at the Crown Hotel on the day of Keltonhill Fair. It was then trotted out, and he saw at once that it was going lame, and he said he would not buy it. He would rely on his own judgment in regard to lameness. If a horse was submitted to a vet. for examination, the examination would be for soundness. He thought this horse was going sound at the time of the auction sale.

The case was adjourned for debate.—*Dumfries and Galloway Saturday Standard.*

Personal.

Dr. CLEMENT STEPHENSON, F.R.C.V.S., Newcastle-on-Tyne, has met with a serious accident. He was attending the Smithfield Show, London, and stumbled over a small staging near one of the cattle pens. He sustained an injury to the thigh, and was badly shaken. Dr. Stephenson was medically attended, and conveyed home to Newcastle. He has since been confined to bed, and attended by a doctor, and is still suffering badly from the injuries; his condition has not materially improved.

Mr. R. J. STORDY Chief Veterinary Officer to the East Africa Protectorate, left Nairobi en route for England some time since. He was travelling overland through Abyssinia with a view to enquiring into the veterinary problems of that country, and if possible establishing a horse and cattle trade between Abyssinia

and East Africa. Proceeding as the agent of the British Government, he is accompanied by Lord Cranworth who has large interests in the East African Protectorate. They expected to arrive at Aden early in December, the overland journey lasting about three months, and are due to reach England about Christmas time.

Dr. CHAUVEAU has resigned the post of Inspector-General of the French Veterinary Schools and has been appointed Honorary Inspector-General.

Dr. CHAUVEAU, who had distinguished himself in Anatomy, Physiology, and Pathology before the majority of us were born, is not going to retire from research work, notwithstanding his great age.

C.I.E.

Lieut.-Col. George Henry Evans, Officiating Inspector-General, Civil Veterinary Department.

OBITUARY.

J. M. WATSON, M.R.C.V.S., Govt. Veterinary Surgeon, Pretoria, S. Africa. Graduated, Edin: March, 1896.

The intimation of Mr. Watson's death states that it occurred early in November, but no particulars are to hand.

EDGAR BELCHER, M.R.C.V.S., 165 Church Street, Kensington, W. Lond: Dec., 1905.

Mr. Belcher's death occurred on Sunday, 10th inst.

JOHN EDWARD TAYLOR, M.R.C.V.S., Piethorne, Rochdale. Lond: Dec. 1871.

Death occurred on Dec. 2, at the age of 61 years.

TREATMENT OF JAUNDICE IN DOGS.

Sir,

Until recently I have always approached a case of "yellows" in dogs, with "fear and trembling" and little hope of success. However, within the last three months I have had 8 cases—3 foxhounds, 2 fox terriers, 2 greyhounds, and 1 borzoi, all of which recovered under the following simple treatment: white of an egg well beaten into a froth, four to eight daily, according to age, size, etc., of patient, 15 grains of concentrated peptone from fresh beef, per rectum, every three hours or oftener, as the case may demand. No other food or medicine.

I would be glad to know if any of your readers have tried this treatment, and if so, with what results.

I would also be pleased to learn if any researches have ever been made with regard to the spread of distemper by fleas, and if not, surely it would be worth a trial; experiments could be carried out quite possibly in some of our veterinary institutions.—Yours truly,

W. T. M. BROWNE, M.R.C.V.S.
Abbeyfield, Naas. Nov. 23.

Prophylaxis and Treatment of Influenza and all Febrile Diseases of Horses.

INFLUENZA ANTITOXIN VETERINARY (P., D & Co.), obtained from the blood of horses which have been immunised against influenza, is a remarkably efficient agent both for the prophylaxis and treatment of febrile diseases in horses, particularly influenza (pink-eye, catarrhal fever or shipping fever) with its complications of cough, laryngitis, bronchitis, strangles, pneumonia and purpura hæmorrhagica.

Mr. G. J. Bissell, who maintains a racing stable in Kentucky, and who has had considerable experience in shipping horses, writes as follows :—

"It is now over two years since I started to use your Influenza Antitoxin as a preventive. Since then I have never had a case of influenza. I have shipped young horses from Canada to Cuba and back. Formerly I carried \$16,000 to \$20,000 insurance on my stable of race horses; now I carry very little, although I have in training from twenty to thirty horses. If it had not been for your Influenza Antitoxin I would have certainly given up a racing stable of horses."

J. E. King, Assistant State Veterinarian, St. Louis,

after four years' experience with Influenza Antitoxin, states that it will abort strangles and cause the tumours to gather and discharge in from 24 to 36 hours, and in pneumonia it enables the veterinarian to save 90 per cent. of those grave cases which invariably die under medicinal treatment alone.

G. W. Dunphy, Consulting Veterinarian of the Michigan State Live Stock Sanitary Commission, states :

"Its power to arrest the action of the influenza toxin seems almost phenomenal."

Practices for Disposal

BUCKS. A good opportunity for a young, qualified V.S., to secure a well established practice, represented as returning (cash) £300 p.a., on average for 16 years. Vendor retiring from profession. Good 8-roomed house and garden, stabling, etc. at £30 p.a. To effect early sale vendor will accept £100. PR. 188.

SOUTH MIDLANDS. A good-class practice in a first-rate sporting district is for immediate disposal. Satisfactory reasons for relinquishing. Returns represented as being over £450 p.a. PR. 119.

EASTERN COUNTIES. An old established practice in good agricultural district is for disposal. Represented as returning about £450. Low inclusive price for quick sale. Nice house and stabling, large paddock. PR. 118

HAMPSHIRE. A partner required for old established practice in fashionable sea-side resort. Returns represented as close on £700. Premium for half share £300, which can be paid by instalments if necessary. PR. 434

CHANNEL ISLAND. An opportunity for acquiring the nucleus of a practice represented as returning about £175 p.a. Great scope for increase. Easily worked at little expense. An offer of about £50 would be accepted for immediate sale, vendor having secured an appointment. PR. 120.

Many Practices are Bought & Sold through our Agency without ever actually coming into the market.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass only.** The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" flat mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Price with 2 Steel Needles in Metal Case—20c.c. 21/- 10c.c. 17/6. 5c.c. 15/- 2c.c. 10/- 1c.c. 9/-

PRACTICES FOR DISPOSAL

PURCHASERS ARE REQUESTED to call, or write stating their requirements, as we have numerous Practices on our Register which have not been advertised. *No charge* is made to purchasers.

To Vendors.

WE make no charge unless a Sale is effected. If you have a genuine Practice you wish to sell quickly and without publicity we shall be pleased to place particulars on our Register.

PROSPECTUS, containing "*Hints to Vendors*" and "*Hints to Purchasers*," post free on application.

SOUTHERN COUNTY. Easily worked practice returning £850 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

LIMITED,

Wholesale Druggists,
40, ALDERSGATE STREET, LONDON, E.C.

Professional Advertisements.

These will be received up to Thursday morning.
Five lines or under 2/6 (exclusive of heading): for two insertions 4/-; for three 5/-; after three 1/- each.
Each line above five—first insertion 6d; after first 3d.
Average—seven words in a line.

These Advertisements will not be inserted unless prepaid, and if replies are to be received at this office an extra sixpence must be included.

As Locum or Assistant

CLASS D student (Dicks), son of V.S., offers services. Town and country practice experience. Disengaged till March. A. Whitelaw Carter, 42 Ash Road, Aldershot

As Locum

EXPERIENCED M.R.C.V.S., will act as locum, town or country practice. Free Dec. 30th. Address, J. B. Taylor, M.R.C.V.S., Shawlands House, by Larkhall, Lanarkshire.

As Assistant

UNQUALIFIED assistant, son of V.S., aged 26, desires post in good mixed town and country practice, permanency if possible. Energetic, good dispenser and book-keeper, and well up in all branches: ride, drive and cycle. Excellent references: previous situation 18 months, disengaged 31st Dec. Address, 4123 V.R., 20 Fulham Road, London, S.W.

As Manager or Assistant

M.R.C.V.S., thoroughly practical, many years experience town and country, desires position as manager or good assistantship, live out. First-class references. Castrate standing, Ride, drive and cycle. Address, 4124 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

FOR country practice, qualified or unqualified, abstainer preferred, to live in. Reply, stating terms to 4126 V.R., 20 Fulham Rd., London, S.W.

Wanted

YOUNG man as assistant, who has seen practice and is a good dispenser. Class C or D man would suit. Address, 4125 V.R., 20 Fulham Road, London, S.W.

For Disposal

OLD established veterinary practice: owner retiring. Address, Campbell, Maesygelly, Rhayader, Radnorshire.

As Manager or Locum

M.R.C.V.S., disengaged Dec. 31st, desires position as manager or locum. Experienced, abstainer and thoroughly reliable, recent references. Address, 3127 V.R., 20 Fulham Road, London, S.W.

For Disposal

COUNTRY practice, good house, surgery, stables, and garden. Returns £150. Rent £24 per ann. Small premium. Address, 2127 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: In bottles, 6d. per dose; minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad), 1s. per dose.

Locum Tenens

MR. WALTER G. GREEN, M.R.C.V.S.

"Rosenheim,"
Boscombe Park,
Bournemouth.

As Assistant

ASSISTANT (1899), steady; will furnish references. Would act as locum. Address, 3117 V.R., 20 Fulham Road, London, S.W.

For Sale

HIGH-CLASS, old established, suburban practice, mixed (chiefly dog), in good neighbourhood: held on lease: brick built kennels. Price £300, to include drugs, instruments and fittings. Well stocked surgery, good introduction, owner retiring. Bargain. Address, 3125 V.R., 20 Fulham Road, London, S.W.

As Assistant

VETERINARY Surgeon, aged 27, desires post as assistant, with view to partnership or succession, in good-class practice. Experienced in all branches: highest references. Interview. Address, 3128 V.R., 20 Fulham Road, London, S.W.

As Locum or Assistant

FINAL year student (29) offers services. Sound experience in town and country practice: Ride and drive horse or car. Free Dec. 15th. S. H. L. Woods, R. V. Coll., Camden Town, N.W.

Assistant Wanted

FOR country practice, must be able to do standing operation, and well up in cattle practice. State age, references. Sign bond. Address, 3121 V.R., 20 Fulham Road, London, S.W.

As Assistant

M.R.C.V.S. (26) requires assistantship in busy mixed practice, Good at parturition: castration standing. Good testimonials. Address, 2129 V.R., 20 Fulham Road, London, S.W.

Practice or Partnership

ADVERTISER, who has £1200 on hand, will be pleased to have particulars of practice or partnership for sale up to that amount, confidence respected, no intermediaries. Address, 2114 V.R., 20 Fulham Road, London, S.W.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

The Journal of The Board of Agriculture

ISSUED on the 15th of each month. Twelve months 4/-, three months 1/-, or single copies 4d., direct from the Board of Agriculture and Fisheries, 4 Whitehall Place, London, S.W., or through any bookseller.

For Disposal

WARWICK, freehold house (or lease) 20 Jury Street. Veterinary surgeon's business carried on upon premises for over 50 years, in main street, country town, good hunting district. 3 reception, 6 bedrooms, bath, large yard in rear. 5 loose boxes, stall, large shoeing forge, saddle room, loft, surgery. Ledbrook, Solicitor, Warwick.

Wanted

RELIABLE, qualified assistant for an extensive mixed practice. State age, height, and give references. Salary £100 per annum all found. Address, 2123 V.R. 20 Fulham Road, London, S.W.

A Bargain in Motor Cars

FIVE seater Humber, 1907 model, 4 cylinder, 10-12 h.p. Hood, windscreen, 3 lamps, Stearns wheel and accessories. Excellent condition. Cost £300, will accept £70. Trial allowed—in Dorset. Apply, C. H. Huish & Co. 12 Red Lion Square, London, W.C.

Replies to Numbered Advertisements

WHEN replies to several of these advertisements are sent to this office at one despatch, it is not necessary that they should be stamped separately: they may be enclosed in one envelope, *but should be marked outside "Replies."*

News Cuttings.

SCRAPS which cannot readily be authenticated either as to origin or date, frequently give unnecessary trouble. A convenient method is to send the page of the newspaper containing the marked paragraph in an unsealed envelope. Postage ½d.

THE FARRIERS' JOURNAL.

A Monthly Magazine for Horse Shoers.
The only paper devoted to the interest of
the Shoeing Smith.

Price 2d., by post 2½d.

London Office: 6 Malden Lane,
Strand, W.C.

Published by G. WILD, 62 Mount Street,
Ashton-under-Lyne.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Gregg's Tracheotomy Tube

MADE in one piece (improved hinged flanges.) The best and the cheapest Tube on the Market. Used by all up-to-date Veterinary Surgeons. Satisfaction guaranteed. Price 15/- Robertson & Co., Victoria Square, Belfast.

CHEAP BOTTLES.

3oz. and 4oz. 6/- per gross, 6oz. and 8oz. 7/-, 10oz. and 12oz. 9/-, 1oz. W. F. Vials 4/- 1½oz. d.o. 4/6, 2oz. d.o. 5/- per gross. Cash with order. All sizes in Poison and other bottles and jars quoted for, also a quantity of 4, 6, and 8oz. named medicals 5/6, 12, and 16oz. 7/- per gross. Carriage paid on orders within 70 miles.

A Christmas Appeal.

Victoria Veterinary Benevolent Fund.

The President and Members of Council of the Fund venture at this season of Goodwill to appeal to the Members of the Veterinary Profession to become **Subscribers of at least Ten shillings and sixpence per annum** to their fund. This sum entitles membership.

The object of this Society is to afford financial assistance to necessitous and deserving Members of the Royal College of Veterinary Surgeons, and to widows and children of deceased Members of the Profession who may be in poverty. The following are some of the persons who are now receiving grants :—

- 1 Veterinary Surgeon, age 85. Only source of income, Old Age Pension.
- 2 Widow of Veterinary Surgeon who died in Rhodesia, 7 children. No income.
- 3 Widow of Veterinary Surgeon, only source of income 4s. a week from son, a motor scout, and 2s. 6d. a week from the parish.
- 4 Widow of a late eminent Scotch Professor, age 84, only source of income Old Age Pension 5s. a week.

And other cases; entailing an expenditure of £150 a year, with only an income of £113 from annual subscriptions. At the next Quarterly Meeting of the Council at least six further applications for relief will be considered, and it is earnestly hoped that sufficient additional funds will be forthcoming to alleviate distress through the winter season.

President: W. FREEMAN BARRETT, Esq., Fountain Court Temple, E.C.

Council :

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1224.

DECEMBER 23, 1911.

VOL. XXIV.

A NEW VETERINARY ASSOCIATION.

To-day we report the inception of a new veterinary society in Connaught. The reason adduced for its formation, viz., the long distances at which its members reside from the meeting places of every other Association, is quite a good one. Of course, one strong Association is far preferable to a number of weak ones, and, however large a number of veterinary surgeons may be within an area in which one Society is accessible to all, that one Society should suffice. It would be a grave mistake, for instance, to found a new Society in London, which could only weaken the powerful one already established there. But the conditions are quite different in districts remote from existing Societies, in which, even though there are few resident practitioners, a union amongst them is more than desirable. The meetings may be less numerous, and the attendances may inevitably be smaller than in some other Associations, but if only a few members determine to make a local Society a success, a success in its own degree it will become. With adequate support this new Society is bound to do good—perhaps a great deal—in its own district, and indirectly elsewhere. To judge from its initial report, that support seems forthcoming, and we trust that it may continue.

FOOT-AND-MOUTH DISEASE.

One of the most noteworthy features in our professional history during the year just closing has been the exceptional frequency of visitations of foot-and-mouth disease. Nearly twenty outbreaks have occurred here—all, of course, being due to the transmission of infection from the Continent—and all have been quickly stamped out.

A Government enquiry has been instituted to determine, if possible, the agents by which contagion can be transmitted. This may increase our knowledge of the vehicles of transmission; but, if it does, it may be found economically impracticable to prohibit the importation of all possible carriers of infection. In that case, and also in the meantime, we may rest assured that the Veterinary Department of the Board of Agriculture can, and will, prevent much harm resulting to us from the prevalence of foot-and-mouth disease in Europe. It is solely due to the efficiency of that Department that the disease is not rampant throughout the kingdom to-day, and in that sense the year, though an anxious one, has been a series of triumphs for our State Veterinary Service. Each successive outbreak has been stifled at its commencement, and though nothing is more probable than that we shall have further visitations of the disease next year, the experience of the last few months teaches us that we have little to fear from them.

"MASSIVE" PULMONARY CANCER.

In man, pulmonary cancer (epithelioma) is a rare affection; and two macroscopic forms of it are distinguished, viz., the *massive* or *compact* cancer and the *diffuse*, *disseminated*, or *nodular* one.

In the first-named form, which is the most frequent, the neoplasm occupies a pulmonary lobe or the whole lung. The pulmonary tissue is whitish, yellowish, streaked with black, like Roquefort cheese, and ulceration is frequent.

In the second form, multiple tumours are found in the lung. The primary tumour is among these, unless the neoplasm is multiple in origin.

Prof. V. Ball records (*Journal de Méd. Vét et de Zootechnie*) a case of massive pulmonary cancer observed in a twelve-year-old dog, which is very interesting on account of the possibility of confusing it macroscopically with pneumonic lesions accompanied by necrosis. It also shows that massive pulmonary cancer may engender mortal complications of the pleura, following upon the ulceration.

During life, the dog in question had shown loss of appetite, emaciation, vomiting, and also respiratory disturbances, especially dyspnoea.

Post-mortem, the opening of the thorax released a hæmorrhagic liquid exudate, which was red, dull, abundant, and fetid in odour. The costal pleura was dull, had lost its polish, and was coloured bright red by the existence of numerous ecchymoses, with a slight fibrinous deposit. The condition was therefore one of hæmorrhagic and putrid pleurisy.

The right lung was affected by passive congestion. The left lung was soft and smooth, and its consistence was firm, recalling that of hepatisation, or more accurately, that of a pneumonia hyperplasic from the commencement. Upon the posterior lobe, about its inferior third and near to the interlobar fissure, was an oval crater-shaped ulceration, disposed horizontally, and about 4.5 inch long, 1.2 inch broad, and 1.3 inch deep. The wall of this ulcer was reddish-yellow and granulating; its edge was rather regular, as if undergoing cicatrization; and its base showed a hæmorrhagic speck. This ulcer had followed upon superficial necrosis of the pulmonary tissue invaded by the cancer, and represented the origin of the pleurisy.

The sectioned surfaces of the cancerous lung showed a homogeneous tissue, yellowish-grey in colour, with dotting and blackish deposits of anthracosis which gave it the general aspect of Roquefort cheese. Sections of bronchi were no longer visible.

Histological examination showed the growth to be an epithelioma, the cells of which were atypical. It seems, therefore, that it should be regarded as broncho-alveolar in origin.—(*Annales de Méd Vét.*)

W. R. C.

CONTAGIOUS PSEUDO-RABIES.

Cadéac describes a disease, the facts of which are culled from numerous original articles published by Hungarian veterinary surgeons, which is unknown in France and termed infectious false rabies. The affection, caused by an invisible virus that cannot be cultivated, attacks the majority of the digestive organs. It gains the system by the alimentary canal in consequence of wounds on the buccal or pharyngeal membrane. It is probably carried by mice and rats.

The incubation is very short. It is manifested by dullness, then continual excitement, pharyngeal paralysis, salivation, sometimes weakness of the hind quarters, and nearly always by violent pruritus at the point of inoculation. It is rapidly terminated by death.

To differentiate this malady from true rabies with which it may be confounded, there is an absence of furious delirium and paralysis of the jaws, the short duration of its course, and the non-virulence of the saliva. It is absolutely incurable. — *Journ. de Méd. Vét. et Zoot.* 30th Sept., 1911.

[Spurious rabies is sometimes encountered in the dog, in which self-mutilation, an insatiable desire to lick certain parts of the body, paralysis of the lower jaw, or delirium of a non-furious character are the chief symptoms. This spurious rabies is encountered in the later stages of distemper, in organic brain disturbance, etc.]

THE CYSTICERCUS CELLULOSÆ IN MAN AND ANIMALS.

According to Vosgien, a French veterinary surgeon, whose brilliant thesis on this subject for the Doctorate of Medicine has just been published in book form. "Measles" in the pig was well known in the time of Aristophanes. Rufus and Aristotle, as well as Aristophanes, recommended the examination of the tongue for the detection of this larval parasite. Albert the Great confounded this disease with leprosy. In the 16th century it was recorded that this disease attacked man as well as the pig, goat, antelope, and sheep. In man the meninges, brain, and subcutaneous connective tissue were its *habitat*. Hartmann, of Königsberg, discovered the animal nature of the cysts. Pallas, Linnaeus, and Fabricius considered they were the larvæ of the *tænia solium*, and Rudolphi gave them, in 1809, the name of *cysticercus cellulosæ*. In 1850 Van Beneden described the transmigration and metamorphoses of these cestoid worms, and the experiments of Hückenmeister, von Siebold and others left no doubt upon this fact.

The *tænia solium* is unknown in the torrid zone, it is frequent in Europe and particularly in Germany where it is as much as 2%. Measles varies from 0.008% in Wurtemberg to 0.244% in Oppeln (Silesia).

In France measles varies from 0.024 in the Bordeaux abattoir to 0.34 in the Parisian abattoirs, and to 0.27 in the abattoir of Limoges.

H. G.

LIVERPOOL UNIVERSITY
VETERINARY MEDICAL SOCIETY.SOME OBSERVATIONS ON BOVINE TUBERCULOSIS
AND A PURE MILK BILL.

By A. B. MATTINSON, F.R.C.V.S.

(Continued from p. 381.)

The essential feature is that tuberculosis be first scheduled under the Contagious Diseases (Animals) Acts and Orders, and the scheme gradually expanded, purely for the welfare of the live stock industry, and independent of any legislation of the Local Government Board.

It is not my intention to go into the scientific side of this question, nor to treat of the future possibility of its control by preventive inoculation, curative sera, animal sanatoria, or other methods of an enlightened future, but to enumerate as briefly as possible a number of factors which I suggest should eventually be considered as bearing directly upon the subject, and all of which will, I believe, have to be taken into consideration in a scheme which has as its foundation the improved health of live stock, and at the same time the safeguarding of the most important live stock products of meat and milk from diseases transmissible to mankind. To allow enormous loss of money to the nation by the neglect of animal health, and to then spend large sums on the inspection of diseased carcasses, savours of the policy of locking the stable door after the horse is stolen. It would appear much more economical, and far wiser, that money should be spent on inspecting live animals and their environment with a view to freeing them from disease rather than in solemnly viewing a carcass ravished by disease, and which exists as a monument to the misleading nature of the proverb that "It's never too late to mend."

The Dairies and Cowsheds Order deals with the environment of cattle, and would be a great factor in assisting the control of bovine tuberculosis if its provisions were duly carried out. This Order should be under the charge of the Board of Agriculture, and should not be administered by the Local, Urban, and Rural District Councils, but by the County Councils direct. The District Councils generally neglect to carry out this Order, and where any pretence is made to carry it out it is generally left to some Nuisance Inspector, who does most of it mentally, and in his office.

Professor Ostertag, in a paper read before the Association of Veterinary Officers of Health, in Glasgow, in September, 1910, concluded his remarks on bovine tuberculosis as follows:

1. In order to effectually check the further spread of tuberculosis in cattle, and to suppress the disease gradually, but comprehensively, State control is necessary.
2. The control must be limited to all open cases, those in the lungs and udder first, and then those in the uterus and bowels.
3. All such cases must be notified.
4. Cattle so affected must be slaughtered with the least possible delay on adjustment of compensation, and their stands and immediate surroundings disinfected.
5. To prevent the spread of tuberculosis by means of milk residue from collecting dairies, skimmed and butter milk and whey must be heated before use as food, and centrifuged slime rendered harmless.
6. Voluntary measures must be encouraged in furtherance of State action.
7. Uniformity of State practice and effectiveness of private action must be secured by the establishment of

a Central Court for the control of tuberculosis in the domesticated animals."

This last I emphasise as an argument in favour of the Board of Agriculture taking over the Dairies and Cowsheds Order, and carrying out this and all their other Acts and Orders through the County Councils, and not by smaller authorities.

The following paragraphs include most of the factors which I believe to be of the greatest importance in the control of this disease, they are merely a crude summary of these factors, and are not intended to be the last word on the subject. Possibly, however, they might reasonably be used as a basis for a scheme for the eradication of tuberculosis in bovines, especially as I believe it would be possible to proceed locally with their application.

LOCAL APPLICATION.

1. *Notification of Disease.* Every person having in his possession or under his charge (1) any cow which is, or appears to be, suffering from tuberculosis of the udder or other chronic disease of the udder, or (2) any bovine animal which is, or appears to be, emaciated from tuberculosis, or which appears to be affected with tuberculosis shall forthwith notify the local authority on the form provided for that purpose (Form A.)

Form A. Full name and address of owner, sex, age or apparent age, colour marks, and breed of suspected animal; owner's valuation; name and address of owner's veterinary surgeon; signed and dated by owner.

2. *Inspection of Suspects.* On receipt of notice (Form B.) from the local authority, the owner of a suspected animal shall permit a veterinary surgeon instructed by the local authority (Form B. 1) to examine such animal and apply the tuberculin test.

The veterinary surgeon shall within seven days forward Form C., duly completed and signed, to the local authority.

Form B. Formal notice of receipt of Form A. stating which veterinary surgeon has been instructed to examine suspected animal.

Form B. 1. Formal instruction to veterinary surgeon to examine suspected animal and to report on Form C.

Form C. Name and address of owner of suspected animal with full description thereof; estimated value; make or brand and quantity of tuberculin injected; temperature chart; report and remarks; dated and signed by veterinary surgeon.

3. *Marking of Reactors.* All animals which are reactors shall, for purposes of registration and identification, be marked by the veterinary officer of the local authority with a numbered earmark, affixed to the right ear, or such other mark, tattoo or brand as the local authority shall from time to time determine, the local authority shall keep a register of such mark or marks together with a full description of the animals marked, such description to correspond with Form C.

4. *Isolation, etc.* All reactors shall be isolated as directed by the veterinary officer, who shall serve the owner with a copy of Form D.

Form D. Directions for isolation, feeding and watering of suspected animals, and for prevention of contagion, time limit and penalties for breach of regulations. Also detachable portion for owner to fill up when requesting an extension of time limit, and space for local authority to reply to such request, giving date of extension if granted.

5. *Feeding of Reactors etc.* When in the opinion of the veterinary officer it is practicable and desirable, reactors shall be fattened for slaughter. In such case the owner shall be at once notified in writing (on the space provided for that purpose in Form D.) of the limit of

time such animal shall be allowed to remain on his premises for purposes of fattening; the owner may within 14 days of the expiration of such time limit request, in writing, the sanction of the local authority for an extension of such time limit, giving the reason for so doing.

6. *Slaughter of Reactors.* The owner of a reactor shall give the local authority seven clear days notice in writing (Form E.) of his intention to slaughter the same; such slaughter shall take place in a public abattoir, or other slaughter house approved by the authority, in the presence of the veterinary officer or some person whom he may depute. The butcher or other person dressing the carcass shall not flay or remove the ear containing the ear mark, nor remove any other identification mark affixed by the local authority.

On the day following the slaughter the veterinary officer shall examine the carcass and take possession of the ear and earmark (or any other mark affixed by the local authority) and shall pass or condemn the carcass wholly or in part as fit or otherwise for human food. That portion which is passed shall be weighed in the presence of the veterinary officer and valued by him. The weight and description of the condemned portion (to which the veterinary officer shall affix an identification mark) shall also be taken, and its *pro rata* value by weight shall also be noted on Form E.

Form E. Formal notice of intention to slaughter, with number and identification mark of reactor; proposed date of slaughter, abattoir or slaughterhouse selected, and time of slaughter. Dated and signed by owner.

Form F. Number and identification mark of reactor, time, place, and date of slaughter, total weight of dressed carcass in pounds (or stones), weight of portions passed and portions condemned in pounds (or stones), value per pound (or stone); total value of passed and condemned portions, report and remarks. Signed and dated by the veterinary officer.

7. *Scale of Compensation.* On receipt of the ear and earmarks (or other mark, tattoo, or brand as the local authority may determine) together with Form F. signed by the veterinary officer, the local authority shall within fourteen days pay compensation to the owner according to the following scale:—

When less than one quarter is condemned, a sum not exceeding £2.

When one quarter in condemned, two-thirds of the value of the portion condemned.

When two quarters are condemned, two-thirds of the value of the portion condemned.

When three quarters are condemned, one-half of the value of the portion condemned.

When the whole carcass is condemned, one-half of the value of the portion condemned.

In special cases approved by the veterinary officer the local authority may also give (in cases where two or more quarters are condemned) a bounty not exceeding one-half the value of the portion condemned.

8. *Immediate Slaughter with Bonus.* In cases where the owner of a reactor is anxious that such reactor should be slaughtered as soon as possible, the local authority may, on the recommendation of the veterinary officer, allow a compensation bonus over and above the scale laid down in paragraph 7. Such bonus shall in no case exceed the sum of £3.

9. *Valuation of Carcass.* In all cases the value of a carcass of a reactor shall be considered to be its value per pound (or stone) multiplied by its weight in pounds (or stones) respectively; the value of the hide and offal shall not be taken into consideration by the local authority but shall be solely at the disposal of the owner. No animal shall be considered of greater value than £20.

10. *Compensation for apparently healthy cattle condemned post-mortem.* Unmarked cattle, apparently healthy and bought *bona fide* for purposes of slaughter at a fair market price, and condemned after slaughter as unfit for human food, wholly or in part, shall be compensated for by the local authority according to scale, viz., two-thirds the total value of the portion condemned. The value of the condemned portion to be estimated as per paragraph 7.

11. *No compensation for worthless animals.* Compensation shall not be paid (except at the option of the local authority on the recommendation of the veterinary officer) for the following animals:

For animals over one but under two years old of less value than £6.

For animals over two or under three years old of less value than £9.

For animals apparently in the advanced stages of tuberculosis.

For calves under twelve months of age.

12. *Branding of aged cattle.* All cattle over seven years of age (or apparently over such age, or which have had more than five calves) shall be marked with an earmark in the left ear (or other such mark as the local authority shall determine) and shall not be moved from the premises whereon they are confined at the time of marking. The owner of any such cattle shall, at his own expense, in the month of May in each year, forward a copy of Form C., duly completed and signed by an approved veterinary surgeon, certifying the same to be free from tuberculosis. Any such animal failing to satisfy the veterinary officer as to its freedom from tuberculosis, shall, on the local authority giving the owner fourteen clear days notice in writing (Form G.) be slaughtered, and the owner shall have no claim to compensation.

Form G. Formal notice to owner to slaughter animal on or before certain time or date, with penalty for non-observance.

13. *Mammary Tuberculosis.*—All cattle suffering from or affected with tuberculosis of the mammary organs shall be marked in a distinctive manner as required by the veterinary officer to the local authority. Such animals shall be isolated and dealt with under Form D. and fattened for slaughter if practicable within a time limit. In such cases the local authority shall not be liable for compensation except when the carcass is condemned wholly or in part as per paragraph 6. Should the owner consent to immediate slaughter the local authority may, on the recommendation of the veterinary officer, grant the owner a compensation bonus not exceeding the sum of £3 (the milk from such cows is dealt with under the Diseases Order 1885.)

14. *Alteration of time limit, etc.* The time during which an affected animal may be allowed to remain on the owner's premises may be altered or withdrawn at the option of the local authority on giving seven clear days notice in writing to the owner (Form H.) The local authority may enforce slaughter within 48 hours on payment of the maximum compensation allowance, together with a sum not less than £1, nor more than £3. Except in such cases the time limit shall not be less than seven days.

Form H. Formal notice of intention to alter date, giving number and identification marks of reactor and original and amended dates of time limit.

15. *Reactors developing acute tuberculosis.* Reactors which are being fattened for slaughter (under paragraph 5), and which develop acute tuberculosis shall be dealt with at the discretion of the local authority under paragraph 14.

16. *Slaughter must be within time limit.* Compensation for reactors branded by the local authority shall

only be paid when such reactors are slaughtered within the time limit, or certified by the Abattoir Veterinary Inspector or his deputy upon the expiration of the time limit. The local authority may order the slaughter within 48 hours of the reactor, and reserve the right to grant or withhold compensation wholly or in part.

17. *Removal of reactors.* No reactor or clinically affected animal shall be removed, dead or alive, from the premises at which it was earmarked or noted to be clinically affected without the consent in writing of the veterinary officer to the local authority (Form I.), and no clinically affected cattle shall be sold or exposed for sale within the selected area.

Form I. Permission to remove reactor (or carcass) from and to specified places on particular date for certain limit of time giving number and identification marks of reactor (or carcass). Signed and dated by the veterinary officer.

18. *Restriction re use of tuberculin.* No person other than a M.R.C.V.S., licensed medical practitioner, or other authorised person shall prepare or keep tuberculin or other allied products in his possession; no person other than a M.R.C.V.S. shall apply the tuberculin test to cattle and no person shall inject or cause to be injected any tuberculin or allied product into any cattle without the consent in writing of the local authority. (Form J.)

Form J. Permission to use tuberculin on specified date for specified number of cattle on certain premises with compulsory notification of reactors. Signed and dated by veterinary officer.

19. *Identification marks not to be defaced.* No person shall remove, alter, obliterate, change or otherwise deface any earmark or other mark, brand or tattoo which the local authority shall affix or imprint, and no person shall remove, sell, expose for sale or be in possession of any animal in which such identification marks have been removed, obliterated or defaced.

20. *Registration of bulls.* All bulls kept for stock purposes or exhibition shall be registered by the local authority: the owner shall annually, at his own expense, in the month of May cause the animal to be examined by an approved veterinary surgeon, and certified to be free from tuberculosis.

Form C. Any animal failing to satisfy the veterinary officer of the local authority as to freedom from tuberculosis shall be dealt with under paragraphs 1, 3, 4, and 5.

21. *Breach regulations.* Any owner of cattle contravening any of these or other regulations laid down for the eradication of tuberculosis shall be guilty of a misdemeanour and shall be liable to such a penalty or penalties as are by statute provided: any such breach or contravention of regulations shall (in addition to the Statutory penalty) entail forfeiture to all claims for compensation from the local authority.

22. *Power of entry of veterinary officer.* The veterinary officer to the local authority shall have power to enter any premises, buildings, fields, enclosures, or any other place in which cattle are housed or kept in which he suspects cattle to be housed or kept, at all reasonable hours on any day including Sunday: any person obstructing such inspector or preventing or attempting to prevent his entry or wilfully obstructing him in the performance of his duties shall be guilty of a misdemeanour, and may on conviction be punished according to the provision of the Statute. Any such person obstructing an inspector and being an owner of a reactor or suspect shall also, if convicted for obstructing, forfeit all claim for compensation in respect to such reactors or suspects.

23. *Power of seizure of apparently clinically affected cattle.* The inspector to the local authority shall have power to seize and impound any cattle which are in his

opinion affected with tuberculosis and to deal with such according to the provision of the Statute.

I trust that the long recital of forms, etc., which I have just enumerated has not conjured up visions of Form 4, Insurance stamps, or other objects sacred to the politician; and I venture to think they are not so formidable as at first appears. No finality of perfection is claimed for them. I give them merely as suggestions for collecting and systematising data which would, I believe, be useful for reference and for further action, and I believe that some such system applied to various definite portions of counties at once to be fairly practicable.

Already I have provided ample material for discussion and humbly request gentle treatment at your hands, so will now draw the paper to a close with a few observations on the Pure Milk Bill of 1910.

The principal objection to this Bill is the dual control of Local Government Board and the Board of Agriculture and Fisheries. I would greatly prefer that the Bill should keep clear of purely agricultural matters and deal only with milk and dairies, leaving live stock, carcasses, and cowhouses to a Bill of the Board of Agriculture. That is all I shall say with reference to the question of dual inspection as a whole—with the following exceptions.

Clause 2, para. 3, states: "If on any such inspection the Medical Officer of Health or the Veterinary Inspector or surgeon has reason to suspect that any cow in the dairy is suffering from tuberculosis with emaciation or from tuberculosis of the udder or is giving tuberculous milk, etc., etc."

I would suggest that this be divided so that the medical officer's powers be limited to a suspicion of a cow giving tuberculous milk, from his examination of samples of milk from such a dairy; and that the suspicion of cattle suffering from tuberculosis in any form be the duty of the veterinary inspector.

Clause 2, para. 8, provides for the withdrawal of an order on a dairyman if the local authority or their medical officer is satisfied that the milk supply has been changed, etc. One may ask if a certificate from the veterinary inspector that the cattle were changed and free from disease would not be better?

Clause 3, para. 2, lays down restrictions on an owner to prevent him allowing a diseased cow being kept along with cows in milk. Clearly such a regulation should be part of a Contagious Diseases (Animals) Act if tuberculosis is to be a scheduled disease. If it is to be allowed to remain in the Milk Bill the attention of the owner should be here drawn to the necessity of immediate notification.

Clause 5 deserves special mention as it glories in the misleading title of "Appointment of veterinary inspectors" and must be quoted *in extenso*: "The L.G.B. may by order require the Council of any County, Borough, or Urban District to appoint or combine with another such Council in appointing, for the purposes of this Act, one or more properly qualified veterinary inspectors, or to employ for those purposes any inspector or other officer appointed by the Council under the Diseases of Animals Act, 1894."

Two vitally important factors stand out in this Clause: firstly, that rural district councils in whose areas the majority of cattle are kept are not included except through the County Councils, and that urban districts where few cattle are kept must provide an inspector. Secondly, the word *or* and those following allow our old and well tried friend the constable, with his accomplices the plumber and retired butcher, to pursue their machinations in the inspection of live stock under this Bill.

One regrets to say it, but some little knowledge of the ways of humbug, patronage, and officialism makes it appear to me that this clause will very generally be interpreted as follows:—

"In places where no nuisance inspector, retired police sergeant, butcher, or plumber resides, and where the finances of the local authority do not permit of a salary commensurate with the duties of this office, the local authority *may* appoint a veterinary surgeon for the purposes of this Act, where such a person is appointed, his salary shall in no case exceed the sum of £20 per annum, and the appointment shall be determinable by a week's notice in writing on either side."

I may say here that the original clause requires little alteration to make it of much more utility and equity, and I would suggest that it be as follows:—

"The Board of Agriculture and Fisheries *shall* by order require the Council of every county, borough, urban and rural district, to appoint, or combine with another such Council (under the direction of the County Council in the case of urban and rural districts and non-county boroughs) in appointing for the purposes of this Act, one or more properly qualified veterinary inspectors."

And concurrently to issue an Order as to conditions of service, salary, etc., of such officers, on the lines of that regarding medical officers of health as issued by the Local Government Board, and as is foreshadowed in this Bill, Clause 6, Sec. 1, para. 2: "The qualifications, duties, salaries, and tenure of office of veterinary inspectors."

Clause 13 provides that the expenses of local authorities under the Act shall be provided out of various local funds and rates. This is highly objectionable, as a dairying district is thus mulcted to provide pure milk for towns and urban districts which receive the greatest benefits under the Act; the only fair and equitable way is that at least one half the cost should be borne by contributions from the Imperial exchequer.

I apologise for the great length of this paper on a somewhat threadbare subject, but it is one of great importance in spite of its antiquity. I have only been able to touch upon it very lightly with a view to raising a good discussion, as probably few subjects are more controversial and yet of equal importance to the farmer and dairyman.

At the conclusion a very hearty and unanimous vote of thanks was accorded to Mr. Mattinson, moved by Mr. Richardson, seconded by Mr. T. Eaton Jones.

On the motion of Mr. Eaton Jones, it was agreed to have the paper printed and circulated, and fully discussed at the next meeting.

The members subsequently had tea together.

ARNOLD RICHARDSON, Hon. Sec.

SOUTHERN COUNTIES VETERINARY SOCIETY.

A special meeting was held at the Holborn Restaurant London, on Wednesday, December 6th. In the absence, owing to illness, of the President, Mr. W. Hunting, Mr. C. Roberts, of Tunbridge Wells, the senior Vice-President, was voted to the chair, and the following also signed the attendance book: Prof. G. H. Wooldridge, Messrs. A. L. Butters, R. F. Wall, London; A. H. Archer, Southsea; E. Whitley Baker, Wimborne; Walter Burt, jnn., J. H. Lockwood, Harold Leeney, Brighton; W. A. DellaGana, Southampton; C. Pack, Lymington; H. G. Simpson, Hampstead; H. Smith, J. Alex. Todd, Worthing; S. H. Slocock, Hounslow; F. G. Samson, Mitcham.

Visitors: Col. L. J. Blenkinsop, D.S.O. P.V.O. Salisbury; Lieut.-Col. A. P. Blenkinsop; Messrs. H. F. Brookman, Worthing; J. E. Overed, and W. Reekie.

On the proposition of Mr. W. Bart, seconded by Mr. Lockwood, the minutes of the last meeting as published in *The Veterinary Record* were taken as read and confirmed.

The Hon. Sec. announced the receipt of apologies at inability to attend from the following: Dr. J. McI. McCall, Maj.-General Fred Smith, C.B.; Messrs. G. T. Angwin, T. Bolton, R. Burt, W. Caudwell, C. J. Callow, W. A. Collins, W. Coveney, J. B. Dier, J. T. Firr, E. R. Harding, F. Marks, P. Perkins, C. Peirce, W. K. Stuart, C. H. Spurgeon, W. Shipley, R. A. Thrall, F. T. Walder, A. C. Wild, and D. Wyllie.

A letter was read from Miss Hunting acknowledging the resolution of sympathy with her father which the Society had passed at their last meeting at Aldershot. The Hon. Sec. mentioned that he had received a telegram from Mr. Hunting asking him to call that morning; that he had called as desired and found their President had been in bed since Sunday, and was not in a fit state to turn out. Colonel Blenkinsop had kindly sent him a typed copy of the paper he was going to read at that meeting, and when he (Mr. Todd) called on him that morning, Mr. Hunting handed him some notes to be read to them with a view to opening the discussion. Mr. Hunting wished him to express his very great regret that he could not be present with them.

Mr. W. Burt moved a resolution of sympathy with their President, Mr. Archer seconded, and the matter was remitted to the Secretary.

A letter was read from Mr. R. Porch, of Bristol, definitely tendering his resignation, as he was no longer able to attend any of the meetings.

The CHAIRMAN explained that Mr. Porch had been written to on two or three occasions urging him to continue his membership, and he had consented to do so, but he took it that this was really final, and that they had no alternative but to accept the resignation with regret.

Mr. BURT proposed that this be done, and Mr. Lockwood having seconded, it was unanimously agreed to.

The circular letter was read from the Association of Veterinary Officers of Health, asking support to a resolution which they had passed at their meeting at Edinburgh on the 13th October last, calling on the Government to immediately take steps for the control of tuberculosis among animals.

The CHAIRMAN took it that there would be no objection to their giving the support asked for by passing a similar resolution, and if this was so he would ask them to signify their assent in the usual way.—Agreed.

A communication from Prof. A. Gofton, Hon. Sec. of Committee, had reference to the scheme for the amalgamation of veterinary societies, and

The CHAIRMAN: Seeing they had already approved of the principle, he took it that all that was required of them now was to intimate their intention of becoming affiliated in accordance with the amended rules.

Mr. BURT asked whether they were justified in taking this course on a communication submitted with the other correspondence, but it was pointed out that special notice had been given of the matter on the agenda, and the meeting then agreed to the Chairman's suggestion.

A letter inviting the Society to appoint delegates to next year's Congress of the Royal Sanitary Institute.

The CHAIRMAN said he understood from the Secretary that there would be plenty of time to deal with this at their next meeting, but if they liked to settle it that day there was no reason why they should not do so.

Mr. BURT asked who were the delegates last year.

The Hon. Sec.: We did not appoint anyone to represent us officially but merely sent a subscription.

Mr. BURT proposed that they adopt the same course on the present occasion; that they subscribe, but do not send any delegate. The expense of sending a delegate would, he took it, be four or five guineas, and seeing that they could get the whole of the papers and the reports of the discussions afterwards, he did not see

that there was much advantage in being personally represented.

Mr. DELLA GANA begged to differ. He thought it would be a most wholesome thing for their Society to be represented at these meetings. He once attended a meeting of a similar nature at Cardiff, and he had reason to believe it did some good. They were becoming influential in a small way as a Society, and he thought they should send a delegate and subscribe towards his expenses.

Mr. BURT: What is the good?

Mr. DELLA GANA: First of all there is an advantage in being represented and being able to take part in the discussions because in that way you get attention. We meet here in our own little shell and nobody knows of us, but if we are represented at these Congresses people get to know of our existence.

Mr. H. SMITH and Mr. Butters also agreed, the latter pointing out that it frequently happened they were able to correct statements made by other speakers in some of the other sections.

Mr. BURT: If the delegates are going to attend the meetings of all the other sections well and good.

The CHAIRMAN: Will you propose, Mr. Della Gana, that we send delegates?

Mr. DELLA GANA: Yes, I will do so with pleasure.

Mr. SMITH seconded, and the same was then put and carried, Mr. Butters pointing out that the actual appointment of a delegate could be left over till the next meeting.

A letter from Mr. W. Shipley, of Great Yarmouth, inviting support for the Victoria Veterinary Benevolent Fund.

Mr. W. BURT, in supporting this appeal, took it that they all knew this Society was doing a lot of good, and personally he thought it was a good way of giving charity, because there was an old saying that charity began at home, and their own profession ought to be nearest to them. He had been on the Committee now for some years, and one could hardly credit the number of widows and other dependents of deceased veterinary surgeons who were left absolutely penniless. The Society could not relieve nearly so many of these as they would like, owing to the lack of means, and they were anxious to get an increased number of subscriptions so that they might have a larger annual to carry on their good work. In a good many charities a lot of the money went in working expenses, but this was not the case here, for there were no working expenses except those of postage and a little printing, and if they could afford to give 10s. a year it would be much better to give it to their own professional brethren than to outsiders.

The CHAIRMAN: It appears to me that this is a private matter for the members individually, but I am sure we hope some of you will become annual subscribers.

Mr. BURT: Better say all.

The CHAIRMAN: Well it would be nice if we were all to do so.

NEW MEMBERS.

Mr. W. W. HENDERSON, of Haslemere, and Mr. T. A. B. COCKSLEDGE, of Emsworth, who had been formally proposed and seconded at the last meeting as members, were unanimously elected.

Brighton, proposed by Mr. Burt, and seconded by Mr. Smith; and Salisbury, proposed by Mr. Della Gana, and seconded by Mr. Pack, were suggested for the next meeting in March, and on a show of hands being taken Brighton was selected by six votes to five.

"THE POSSIBILITY OF PREVENTING THE PRESENT
CONFLICT OF VETERINARY EVIDENCE IN POLICE
COURT CASES."

By Colonel L. J. BLENKINSOP, D.S.O., A.V.S.,
(P.V.O. Southern Command.)

Gentlemen, - I must thank you for the honour you have done me in asking me to address your Society. I wish that the task was in more worthy hands, as I am afraid that my experience in Police Courts is distinctly limited, as a witness, expert, or otherwise, and I have not had the doubtful privilege of appearing before a Court of Justice in an even less enviable position. However, I come here to learn, not to teach, and I hope my remarks may give rise to a profitable discussion which will lead to definite conclusions.

I venture to put before you some very crude remarks on the subject of veterinary evidence, for I feel convinced that it is a question of the highest importance to our profession that the expert testimony of its members should be beyond reproach. The general estimation in which veterinary surgeons are held by the public depends very much on the impression made by them when called as witnesses in the Law Courts. It is as well, therefore, that they should conduct themselves on these occasions in such a manner as to earn the respect of those who hear them, as well as the many more who will read the report of their evidence in the newspapers.

As expert witnesses we have the great privilege of being able to express our opinions on any point before the Court which may come within the range of our special professional knowledge, whereas in the case of ordinary witnesses such opinions and beliefs are not admissible as evidence. In the latter case it is for the witness to state the particular facts within his knowledge and for the jury to draw their own conclusions regarding the accuracy of his statements and their bearing on the case at issue.

I am not proposing to give you an amateur disquisition on evidence, but I wish to put before you certain points which may help to obviate the conflicting opinions which are now unfortunately given in evidence on veterinary questions by members of our profession. So long as medicine is not an exact science opinions must differ in many cases as to the interpretation of facts. People may even fail to describe facts accurately. It is almost a commonplace that persons seeing an incident and having the same facilities for observation, will describe what they have seen, not only in different language, but also with more or less marked discrepancy as to details of the event. An experiment made by a professor of medical jurisprudence in Germany illustrates this point to perfection. The professor caused a man to come into his lecture theatre armed with a revolver, aim the weapon at him, fire a blank cartridge, and leave the room. The class was then told to write a detailed account of what they had seen. The reports were found to differ widely, even in the essential details. If one is investigating a case and two or more witnesses give almost identical evidence, and especially if they use several identical phrases, one is at once suspicious of collusion.

Again, we cannot get away from the fact that some people have vivid imaginations, and that they are apt to confuse incidents which they have observed with the creations of their minds, or to enlarge indefinitely on a small substratum of fact—and to do so in all innocence. A good example of this tendency is to be found in "Martin Chuzzlewit": "The chambermaid in the back ground made out as much of the letter as she could and invented the rest, believing it all from that time forth as a positive piece of evidence."

As professional men we cannot be too careful in sifting out our opinions before venturing to express them in the Law Court. Careful notes made at the time are the

best means of obtaining premisses from which to draw conclusions. Mr. Gladstone said "The best memory is a record made at the time," but in making such a record it is very necessary to be extremely careful in the wording of it. It is surprising how few Englishmen who have the ordinary public school education appreciate the meaning of the words of their language, and who are therefore unable to express ideas with accuracy and lucidity. I would suggest that the careful recording of clinical cases by students would be of the greatest assistance to them in their future career, especially if these clinical notes were corrected and criticised by the teachers at the time, or shortly after they were made. I believe this practice would assist men in learning to make accurate and scientific deductions from clinical facts, and would also teach them the true significance of words. Jenner said "More mistakes, far more, are made by not looking than by not knowing," and it is this particular faculty of "looking"—accurate detailed observation—which goes far to effect the evolution of the successful practitioner.

It should not be forgotten when giving evidence "that successful barristers are men whose training enables them to pick up very quickly a certain amount of knowledge of any subject, and it will not do to rely upon their ignorance." If a veterinary witness really understands his case he need not be afraid of any barrister, so long as he keeps his head and does not get flurried.

"Expert witnesses are allowed to refresh their memories in court by references to treatises which they are in the habit of consulting. But as such treatises do not thus become themselves evidence, a witness is not entitled to read aloud from them but must embody the result in his own words and give evidence on the matter on his own responsibility." Similarly, a witness under examination may refresh his memory by references to notes made by himself at the time of, or soon after, the transaction on which he is being questioned. He may also refer to any writing made by any other person and read by the witness at the time, if, when he read it, he knew it to be correct. This reference in court to notes and treatises will assist witnesses to be accurate, but it should be borne in mind that any such writing must be shown to the opposite side if it is required, and that it is open to them to cross-examine the witness on the documents to which he has referred.

In giving evidence the veterinary surgeon should express himself in the least technical language possible, and he should also remember that stable and farm expressions are often even more difficult for the court to understand than accurate scientific terms. It is to the use of loose unscientific horsemen's terms that I attribute a great deal of the unsatisfactory evidence which is frequently given, and I submit that if a nomenclature of animal diseases, based on scientific teaching, was drawn up by authority of the Royal College of Veterinary Surgeons, it would greatly assist towards the use of similar terms for definite pathological conditions by veterinary surgeons giving expert evidence in law courts. At the same time I do not for a moment advocate the use of the technical terms. We all know the story of the doctor who, when giving evidence in an assault case, described the injury received by the plaintiff as "a contusion of the orbit, accompanied by subcutaneous ecchymosis." "If you mean a black eye," said the judge, "why not say so, and make yourself more intelligible to the jury." No, in the law courts one should use English undefiled by horsey slang or scientific jargon.

With respect to the evidence which a veterinary surgeon decides to give, Saundby in his Medical Ethics says, "Let him imagine that he is going to address a medical society, and say nothing he would not feel sure would meet with the approval of his medical brethren, if in doubt about any pathological or toxicological point he should admit the doubt." This admission is far more

dignified and will frequently give more weight to evidence than dogmatic statements on debatable subjects. Although to "bluff" the court, if I may use the expression, is derogatory—unfortunately such behaviour is not unknown, and instances have occurred where veterinary witnesses have gone so far as to back their evidence by offering to pay certain sums of money if it is proved that what they are stating is incorrect.

The exaggerated and emphatic terms used by witnesses frequently make one doubt whether they can fully appreciate the true significance of the words they employ. Conclusions should be moderately stated and due weight given to any facts which tell against the client in whose interest one has been called, as the court is more liable to be guided by a witness who is evidently fair than by one who shows bias.

A veterinary witness should under all circumstances be eminently fair, and he should maintain the independence of his opinions—he should not allow himself to become an advocate for one party or the other. When approached regarding the case, he should give his candid opinion and absolutely refuse to have his opinions suggested to him. If he is called as a witness on these terms, well and good; but, if after having been consulted as an expert on one side, he is informed that he will not be called, he should refuse to give evidence for the other party should he be approached by him, as he could not well avoid making use of information which he had acquired when he stood in a trusted position to those who first consulted him.

Great care should be taken when giving evidence in cases where another veterinary practitioner's conduct or skill may be called in question, not to display any bias or professional rivalry. In examining patients or making post mortem examinations under such circumstances, it is our duty to give the professional brother who may be implicated the opportunity of being present, and to allow him, should he desire it, to be accompanied by a pathological expert. In giving evidence the witness should tell the truth without straining the facts for or against his brother practitioner but, if any doubt exists, he should give him the benefit of it.

Avoid writing unofficial opinions—remember what Stanley Atkinson said, "Do right and don't write—then fear nothing."

In consultation, be open and straightforward with your professional brethren. I am firmly convinced that more ill-feeling and bad-fellowship has resulted in our profession from reticence and shifty behaviour of practitioners in consultation, than from any other cause. I would ask one and all to remember that the respect of their professional brethren is of far more real value than any petty fees or short-lived popularity obtained from laymen whom they may have endeavoured to help at the expense of a colleague. Think twice before adversely criticising the opinion, diagnosis or treatment of another veterinary practitioner, remembering that clinical symptoms and signs may alter from day to day, thus explaining apparent discrepancy. Stringent criticism is more often the result of narrow ignorance than wide knowledge. One of the greatest teachers of surgery of his day (Mr. Christopher Heath) used to say, "The man who has seen the greatest number of fractures will be the last to criticise the results obtained by other surgeons." We should recognise ourselves to be integral part of our profession, and then we shall feel that any disparagement of our brother practitioners before the public reflects quite as much upon our status as upon that of a colleague we may be inclined to criticise adversely.

There is a homely saying that it is a dirty bird who fouls his own nest. If we belittle our professional brethren's opinions we are shaking the public confidence in veterinary science, and in so doing we are lowering our own standing. I would ask of you that you should not too readily jump to the conclusion that one or other

member of the profession is wilfully giving false evidence because there is a divergency between their statements—at the same time one cannot but recognise that unfortunately there are cases in which veterinary surgeons make statements in the Law Courts which are flagrantly at variance with obvious facts, and with the incontrovertible dicta of science. It is only in these cases we can hope definitely to prevent the present conflict of veterinary evidence in the Courts. There is no excuse for expert evidence being given on these lines. An expert may refuse to give evidence on expert opinion, although if called to speak as to facts, he cannot, of course, refuse to testify. He is not, however, required to depose to facts with an expression of such certainty as to imply that all doubt is excluded from his mind. It should be remembered that it has been ruled that a man who falsely swears that he "thinks or believes" is equally liable to conviction for perjury as is the man who swears positively to that which he knows to be untrue.

Discrepancy in veterinary evidence could be avoided by a consultation, and such consultations should be always welcomed or even suggested.

Disciplinary action should be taken by the Royal College of Veterinary Surgeons in all cases of flagrantly unsatisfactory veterinary evidence, and, having set our house in order, we should jealously guard it against disparaging remarks and insinuations—no matter by whom they may be uttered. At present we appear to be asleep, and, sad to say, our professional veracity is fast becoming a byword in the Law Courts.

Having given expression to these few scattered thoughts on this most important subject, I shall now place the matter in the hands of the members of the Society for discussion. I hope to learn much from your President, Mr. Hunting, whose evidence in the Law Courts always carries weight and conviction, and I hope that several other gentlemen present will give us the benefit of hearing their views.

The subject before us has a wide bearing, influencing as it does our credit as a profession and our individual position in the eyes of the public in general, and of our clients in particular.

DISCUSSION.

The notes made by the President (Mr. W. Hunting) as an opening contribution to the discussion, and to which reference had been made earlier, were read by Mr. Todd as follows:

"Colonel Blenkinsop has given us a good opening for our discussion. He has taken no side, but warned us all of the pits and traps which may waylay us in the courts. The Colonel's advice is good—"know what you are talking about and tell the truth, and you need not fear facing counsel."

But even if we are all knowledgeable and honest men, I think we shall have differences of opinion expressed in the witness box. These differences may not be very wide apart, but they are carefully driven asunder as far as possible by able counsel.

Everyone distinguishes evidence as to fact from evidence on opinion, but even facts are not always clear in dealing with changes in an animal body. Mr. Plowden is reported to have complained that "one veterinary surgeon said the horse was lame on three legs, another said it was lame on two legs, and a third denied that it was lame at all." Unless some of these men were misusing words and drawing mental distinctions between stiffness and lameness, it is not easy to answer Mr. Plowden's complaint. There are in all callings some black sheep, and some of our experts are simply liars. There ought not to be differences of opinion as to whether or no a horse is lame, but there may be vast difference of opinion as to the cause, seat, and nature of the lameness.

A recently reported law case turned upon the question—whether the mare had ringbone. Some half-dozen good men appeared on each side, and one half-dozen swore there was no ringbone, whilst the other half-dozen swore there was. I carefully read the evidence as reported and failed to discover what pathological condition was being referred to—was it a mere periostitis on the phalangeal bones, or a true articular disease surrounded by a growth of bone—a true ringbone. It seemed to me possible to reconcile the diverse opinions by supposing that there was no real ringbone but a use of the word as meaning—any enlargement about the pastern.

But this case is unique for something more than a difference of opinion. The report states that more than one professional witness expressed the opinion that the "condition he found could not be overlooked by any qualified practitioner." Feeling quite uncertain as to what the pathological lesion was at Dumfries, I should like to say that unless a ringbone is developed there are cases in which any two men may disagree and yet know their business.

I cannot help thinking that a good deal of apparently contradictory evidence would cease at once if we all agreed not to use the expression "false ringbone," and to confine the term "ringbone" to a state in which articular disease existed.

Reports of law cases show that veterinary witnesses have as much trouble with hocks as they do with feet. Whether a horse has spavin or only coarse hocks is an old controversy, but one in which age does not make it more venerable. The question is chiefly one of definition, but there are cases so on the border line that the very ablest man may be deceived.

Again, mistakes may be made about curb. A little bony enlargement on the outside of the hock may give to the eye all the appearance of curb, and require careful manipulation of the ligament to remove the first impression. In a case of this kind perhaps the first impression is mentioned—some weeks elapse, an action commences, and the V.S. delivers his proof to a lawyer. After that it is not easy to run back, and our time in the witness box is spent in uncomfortable fencing or—worse.

One would expect that evidence in the High Courts would be less objectionable than in the Police Courts. The High Court case takes longer to prepare and come on for hearing. The witnesses' evidence is taken by the lawyer's clerk, who suggests an adverb when you don't want to be too positive, and who somehow has embued your evidence with his own notion of the case by the time a final proof reaches you. Then counsel takes you quite as far as the proof warrants, and opposing counsel lays in wait for any exaggerations or omissions.

Now in Police Courts there is less time for carefully prepared proofs of evidence, and consequently for the elaboration of theories and the squaring of difficulties. If men of the same calibre appeared at Police Courts as at the High Court I think the Court of first instance would often obtain the greatest help to justice from expert evidence.

After all, the suspicions thrown upon our expert evidence is more due to the ignorance of the suspects than the wrongs of the experts. Our evidence is chiefly a matter of opinion, and some allowance must be made for differences of opinion. If it were matter of fact it would be very different.

A witness may be asked the length of a stick, and his opinion may be six inches wrong.

Our expert may be asked a question which turns upon the sensation to his finger of some change represented by a small fraction of an inch.

Is it any wonder men differ on such points?

Mr. W. BURT remarked that it seemed to him that the great difference of opinion which was the cause of the profession being held up to ridicule occurred more in the police courts and not so much in the High Courts. In those cases where a horse was stopped by one of the Society for the Prevention of Cruelty to Animals' men, or by the police, the horse generally was lame, and yet in a large number of these cases they would find veterinary surgeons willing to come into court and say that the animal was not lame. The question as to whether a horse was lame was one on which there could be or should be no two opinions. He granted that they must allow a certain amount of latitude for difference of opinion as to the extent or cause of the lameness, but there ought not to be this great divergence of opinion as to whether the horse was lame or not. Mr. Hunting in his notes had used the word "stiffness," but he contended that stiffness was a degree of lameness, not absence of lameness. He happened to be the police veterinary surgeon for Brighton, and they got one or two of these cases perhaps in a month, but he could only say this, that if a man was to say an animal was not lame when as a fact it was distinctly lame he should never speak to that man again. After all he did not believe horses were stopped because the policeman or the Society's man fancied they were lame; they might accentuate the lameness in their mind, but as a general rule they did not stop a horse unless it actually was lame. They might do so occasionally, but it was very unlikely, and when both the policeman and the veterinary surgeon agreed, he said for another man to get up in the witness box and say the animal was not lame was disgraceful. And yet this frequently happened, especially in the London Police Courts. He did not know whether they were a different class of men in London or not, but when they did this sort of thing he should put them down as what Mr. Hunting said, liars, pure and simple. It was these cases that were so detrimental to their dignity as a profession, not the cases in the High Courts, because the cases that engaged the attention of the High Courts were cases for the most part for expert evidence. He had in his mind a case in which there was what they were pleased to call mechanical lameness. There was a lameness, but the animal was not suffering any pain. He believed it was eventually boiled down to this, that there was only one form of mechanical lameness, arising from the shortening of the back tendons of the hind legs, but he contended that if an animal with short tendons was to go lame it must be suffering pain. After a time there must be perhaps first discomfort but eventually pain; and a horse should not be subjected to any pain when working. To go back to the subject of the paper, however, for a veterinary surgeon to say a horse was fit for work when it was lame was a thing that ought to be punished by the College.

Prof. WOOLDRIDGE rather thought Mr. Burt had put up his views for them to shoot at, because he could not think that he really meant to take such an extreme line. To suggest that no horse that was affected with any degree of lameness was fit for work was a view he thought very few of them would hold. He considered there were plenty of horses with a slight degree of lameness that were perfectly fit for work, and which should be worked without a man who expressed an opinion to that effect being in danger of getting crossed off the rolls. Then with regard to the question of mechanical lameness, here, again, he disagreed strongly with Mr. Burt. If a horse was suffering pain from any lameness that pain must be conveyed by the nervous system, and if there was no nerve supply to the particular seat of the lameness then there could be no pain. It was quite possible for a horse to be lame in a certain place from mechanical causes. If he was unnerved he would remain just as lame as before, proving that the lameness was mechanical, and being strong presumptive evidence

that the horse was not suffering pain before unnerving. Surely one was perfectly justified in saying that such a horse could be worked without cruelty.

Mr. BURT: After neurectomy has been performed, yes.

Prof. WOOLDRIDGE: But these are cases of mechanical lameness which were included in the special terms to which you referred. Continuing, Professor Wooldridge said he should like to thank Colonel Blenkinsop for the very able way in which he had brought this paper before them. It was a paper which they could read at their leisure afterwards, and which would give them food for a lot of thought: and he agreed with him, and also with Mr. Hunting, that one of the greatest things they had to contend for was a recognised nomenclature which could be utilised by veterinary surgeons generally. There was the distinction between false and true ringbone, for instance. It was the use of such terms as these that gave rise to so much of the differences of opinion of which they had heard. Then with regard to the use of the powers of observation they must remember that these powers were not equally developed in all people alike. They could get a very eloquent example of that any day at the College by watching the students examining a horse's legs. What appeared to some to be a very clear and obvious irregularity of the surface would be not be felt or appreciated by others: and he thought very often that the difference of opinion expressed was due to this difference in the ability to observe rather than to any wanton prevarication on the part of the persons expressing those views. But this would not apply to those cases which were so constantly coming before the courts where there was undoubtedly gross exaggeration. These were the cases they had got to fight against, and he thought it was to these that Col. Blenkinsop wanted to draw attention. Only recently a case came before one of the London Police Courts in which the veterinary surgeon on behalf of the police gave evidence that the horse was suffering from lameness, that it was cruel torture to work it, and in fact that he had never met with a more flagrant case of cruelty, while the veterinary surgeon on the other side said the horse was merely stiff and not suffering any pain, and that it was fit to work. The Magistrate said it was impossible for him to come to a decision in the face of the evidence of these two expert witnesses, and he adjourned the case. The police sent up to the College and an impartial opinion was asked for on behalf of the magistrate. He had the case in hand and when he went to give evidence at the adjourned hearing he had no idea of what had been said by either of the two men previously, but he gave his evidence as he thought perfectly just, and after he had finished the magistrate called for the evidence given by the two men at the previous hearing to be read over and then said "I see you agree with both of them." The magistrate had previously been unable to reconcile the apparent conflict of evidence, but his own impartial evidence, taking as he did a middle course, had given him the clue to reconciliation. With regard to another suggestion made by Mr. Burt that the police did not stop a horse because they merely *thought* it was lame, but that they were always *sure*, he did not think he could quite agree with that, because he had seen horses stopped in London which had certainly not been lame. They had been old horses and had not exactly the same freedom of action that a younger animal would have, but they had not been lame. But the police had stopped them, and the man in charge had been summoned afterwards for subjecting the animal to cruel torture. This was how the summonses were usually worded, and these were the words he objected to, because there might not be cruel torture, and the phrase conveyed such a lot to a magistrate. Nobody objected more than he did to cruelty to horses by working them in an unfit condition, but at the same time he thought the police in excess of their

zeal and the Society's inspectors, not merely occasionally but frequently, allowed their enthusiasm to override their judgment.

Mr. BURT remarked that he had said that no horse that was lame was fit to work, and he still adhered to that. Prof. Wooldridge rather suggested that there were horses lame that were fit for work, but he must entirely disagree with him there. To speak of lameness after neurectomy was simply playing with words. What he had referred to had been mechanical lameness before neurectomy. With regard to the cases in which horses were stopped by the police, what he had said was this, that if the policeman who stopped the horse said it was lame, and the veterinary surgeon who was called in agreed that it was lame, no man ought to get up and say it was not lame. He saw a good many horses that were stopped by the police in Brighton, and if there was no cruelty he told the police so, and the case did not go any further.

Mr. H. G. SIMPSON remarked that he should like to say a few words as a visitor, although he confessed he did so with some little diffidence after what had fallen from Mr. Burt. He was unfortunately in the position of being a London veterinary surgeon—(laughter)—although he was in rather a happier position than the average London practitioner, inasmuch as his duties were confined to one firm. Speaking on this very wide question he should like to say first how much indebted they were to Colonel Blenkinsop for bringing such an important matter forward, and to his mind it was an important matter, because they read in the papers morning after morning of cases in the police courts in which they had this great divergence of opinion. His own experience of the police and the Society's inspectors had been in the majority of cases to find that they were very fair, but there were times when a policeman who was not very busy on his beat and wanted something else to do, would stop a horse practically for the fun of the thing; and when this was done that was the horse that would get them into trouble, because the policeman had got to back up his evidence, and at the present time he was sorry to say he seemed to have very little difficulty in finding veterinary surgeons who would back up his evidence. In fact some of them would go a little further and pile their own evidence on top. In London it was the practice to take the cases direct into court if the magistrate happened to be sitting, and the result probably was that before the owner had time to get down to the court the case had been heard and the man convicted. He had a case on one occasion in which a horse had been stopped for a sore shoulder, and before he had time to get down to the court and see the animal the case had been disposed of. In this particular case the veterinary surgeon who was called in for the prosecution not only gave his evidence in an exaggerated sort of way, but in addition he said the horse was incurably lame and not fit to be worked in the streets of London. He could only say his own powers of observation might not have been very penetrating, but he did not consider there was any lameness about the horse. It never had been lame, and to his knowledge it had been working in the streets of London practically ever since the shoulder got all right again. And this was only one case of many. While on this question of veterinary evidence he would also like to say a word on the question of wounds. A case came into court and the evidence was that the horse had a sore shoulder. They did not dispute that, but they very often had the exaggerated evidence that the collar was stained with blood and matter. These terms suggested that the wound was a very old standing one, because they did not get matter formed in a recent wound, and he very much questioned whether any veterinary surgeon could go into court after seeing a case for the first time and absolutely swear that it was blood and matter that was adhering

to the collar. But the words blood and matter conveyed to the magistrate that it was a serious case, and he would deal with it accordingly. He had no grudge against veterinary surgeons taking up these cases, because they all had their living to get, but they could not get away from the fact that it was to their interest to back up the cases put in their hands by the police, and that there was consequently a temptation to them to allow their interests to outrun their discretion. The same thing might also be said to some extent of those who appeared for the defence. They were called in by the client to get the man off, and he was afraid that sometimes it was not so much a question of giving absolutely fair evidence as of giving evidence that would assist in getting the client off. To return to the paper, he should like to see it circulated and for them to have some sort of round table conference and see if they could not deal with this matter. If they did this he thought they would owe a debt of gratitude to Col. Blenkinsop for the suggestion. He had called attention to the present unsatisfactory state of things, and it was up against the whole of the profession to put their heads together and see what they could do to remedy it.

Mr. BURT wished to explain that he had had no desire to run down the London veterinary surgeons; he was simply twitting them (laughter) although after what he had just heard he was still more glad he was not a police veterinary surgeon in London.

Mr. SIMPSON remarked that he did not wish to suggest for one moment that any veterinary surgeon went into court to perjure himself, but a man had to consider his own interest, and it did not always do to go into court and lose cases.

Mr. WALL thought that in a great many cases the police in London were actuated not so much by humanitarian principles as by what they were going to get out of it, and that was a very regrettable state of affairs. From his own experience of the veterinary evidence in the London police courts, he also believed they would find the magistrate was always inclined to favour the veterinary surgeon who attended the court regularly. There was another point, too, he should like to mention. In cases of cruelty they would naturally expect the policeman to call in the services of the nearest veterinary surgeon, but this was very seldom done. In fact he had known them go miles out of their district and pass several other establishments in order to get their own special veterinary surgeon; and we could only draw our own conclusions from that. In his own district he did not happen to be a favourite with the police and he was rather thankful for it, but he had an instance a little while ago which went to illustrate what he had just said. A donkey met with an accident almost outside his door and that animal was left there from 7 o'clock in the morning until nearly 11 o'clock before the police veterinary surgeon put in an appearance. He wanted to know who was guilty of cruelty there. To revert for a moment to the subject of the paper, he thought the cases where the greatest difference of opinion existed were those in which there were contracted tendons, bent legs, or dropped soles; and in London the veterinary surgeon who was called in for the prosecution usually tried to make his evidence fit in with the case. They could forgive a layman like a policeman, or even a Society man, for stopping a horse that was affected with dropped soles, because they all knew that such animals had a most peculiar gait, but it was different with a veterinary surgeon. He admitted that in a number of these cases there was lameness, but in the majority of them he did not think there was any lameness at all. Again, with regard to horses with bent legs, he had known of people being prosecuted for working horses with bent legs which he certainly should not have regarded as being lame. Mr. Burt had mentioned contracted tendons, and he also thought that in many cases

this was only a mechanical lameness. If the horse was shod with an ordinary low, level shoe it might be subjected to pain, but if the space between the ground and the heel be filled up with a calkin on the shoe he did not believe that horse was in any pain whatever. There was one other thing which he should like to see the attention of the magistrates drawn to, and it was this. A man had his horse stopped and he was charged with cruelty. That horse might be walked anywhere up to a couple of miles to a greenyard and left in the yard all night without the slightest attention beyond what was absolutely necessary, in order "that the animal might look as bad as possible in the morning." He had endeavoured to point this aspect of the matter out to different magistrates whenever he had had the opportunity, and he thought it would be a very good thing if other veterinary surgeons were to do the same. He also thought it would be good if veterinary surgeons were called in rotation for these cases. They would be more likely to get an unbiassed opinion, fairer to the owner and fairer to the police, and he was sure they would not get so many prosecutions.

Mr. DELLA GANA said his own experience had been that the police and the Society invariably employed one and the same man in the courts, and his impression was that these men were paid to do what they were told. Moreover, they always seemed to have the sympathy of the Court with them. The defending veterinary surgeon got very indifferent attention compared with that paid to the man who appeared on the other side, and for this reason he now refused to go into court on any of these cases.

Mr. WALL: Might I make one more remark. Colonel Blenkinsop suggested a consultation before going into court. I may say that I have tried, not once but on a number of times to get into consultation with the veterinary surgeon for the prosecution, and although things have apparently gone smoothly before he gives evidence, I have found that when he gets into the box he is absolutely dead against you.

Mr. SAMSON remarked that they had had a most interesting discussion, and the state of things which had been disclosed wanted a deal of rectifying. There was a great deal in what had been said about the police and their ways. It was only about a fortnight ago that a client of his had a horse stopped within thirty yards of his gateway while drawing an empty cart. The man had been sent out with instructions to see how the horse went, and there was no intention of working it, but the police stopped it, as he had said, within a few yards of the owner's gateway, and the animal was kept standing there for two and a half hours while the officer went for his own veterinary surgeon. It was quite true what their friend had said as to there being certain veterinary surgeons who got their living wholly and solely by running about after the police and the Society's men, and personally he thought it would be a good plan if the certificates which these men were asked to sign were sent up to headquarters direct without either the police or the Society's inspector seeing them at all.

Prof. WOOLDRIDGE pointed out that these certificates were not accepted as evidence.

Mr. SAMSON: I know the certificates are not put in, but they will swear black and white to all that is on the certificate. Continuing, Mr. Samson said there was another thing he objected to. Why should these Society men be allowed to give evidence which a veterinary surgeon only ought to give, and also to cross-examine the veterinary surgeons themselves on their evidence. It seemed to him that these men frequently acted both as lawyer and expert witness, and he was surprised that the magistrates allowed it.

Mr. E. WHITLEY BAKER desired to say how pleased he was to meet Colonel Blenkinsop that day. He had not seen him he believed since their student days, and it

was a great pleasure to meet him again. He also wished to thank him for the able manner in which he had handled a subject of so much interest to every member of the profession. He would like to support what Mr. Della Gana had said as to the sympathy of the Court being with the prosecuting veterinary surgeon, and if he might make a suggestion it was that they should try and approach the proper authorities and see if they could get an opportunity for these cases to be reheard without the excessive cost that usually fell on the individual who made an appeal. He had always endeavoured to treat his professional brethren in a gentlemanly and courteous manner, and he quite agreed with every word that had fallen from Col. Blenkinsop that they should if possible consult with their fellow practitioner before going into court. He thought that if they did that more frequently there would be less trouble, although with human nature what it is, he was afraid these differences of opinion would continue to occur. There was one other thing he should like to say. He did not want it to go forth that they were the only offenders in this respect. The same thing occurred in the medical world, and with all due respect to Mr. Plowden, he should like to say there was far more difference of opinion in the legal profession than ever there was in their own.

Mr. DELLA GANA thought, with reference to Mr. Samson's remarks, that the procedure adopted was this. The veterinary surgeon was asked by the Society's inspector to give a report, which was usually done in the form of a certificate, and that that certificate was then placed before a committee in London, who decided whether or not a prosecution should ensue.

Mr. SAMSON: But the veterinary surgeon does not send it up. The officer does that, and in a great many cases he also decides how it shall be filled up.

Mr. BUTTERS, after expressing his thanks to Colonel Blenkinsop for giving them such an interesting paper, remarked that he merely wished to refer to one point, and that was consultations before going into court. Not so very long ago there was a prosecution for lameness in a London police court in which he had an opportunity of having a consultation with the veterinary surgeon on the other side, and he told him before they separated "If you state what you have stated to me there will be no defence, but if there is any exaggeration I shall have to contest it." When the case came on the veterinary surgeon for the police gave his evidence in what he considered was a very fair way, and a small fine was inflicted without there being any conflict of evidence. He thought this was a point which might be considered more often than it was; in fact he had frequently pointed out to his clients that it was much the cheapest way to simply go and plead guilty, especially if they could be sure there would be no exaggeration on the other side.

Prof. WOOLDRIDGE mentioned that there was an arrangement arrived at in Dublin some time ago which he believed worked very well indeed. The Society there had the same topic under consideration, and it was thrashed out, with the result that the members eventually decided to offer to give their opinion free on any case that might be brought to them in the first instance. Of course if a case afterwards went into court the veterinary surgeon was paid his usual fees, but he had reason to believe that quite a large number of prosecutions were avoided by this means that would otherwise have engaged the attention of the courts. He did not know whether some such system could be adopted elsewhere, neither did he know whether it was still carried on in Dublin.

Mr. PACK said there seemed to him to be two reasons for this conflict of evidence. One was the spirit of antagonism which, he was afraid, possessed all of them more or less, and the other was for want of knowing each

other better; and if there was one thing which tended to remove the latter cause more than another it was such meeting as that, where they met their fellow practitioners, and were able to express their views in a perfectly friendly and amicable manner. So far as he was concerned he was pleased to say the police courts troubled him very little, but the police had sent to him occasionally, and asked his opinion as to whether there should be a prosecution or not, and if he had replied in the negative nothing more had been heard of the matter. With regard to mechanical lameness, there was not the slightest doubt it was possible for there to be mechanical lameness without the horse suffering any pain, and he had had an illustration of this himself only recently. He happened to slip one day and sprained his ankle, with the result that he walked decidedly lame for some time, but he could walk for several hours without feeling any pain.

The CHAIRMAN, in summing up the discussion, expressed the pleasure he had derived from hearing Col. Blenkinsop's paper. There were many points in it of great practical value and which afforded food for reflection. With their permission he would ask Colonel Blenkinsop to reply to the discussion.

Col. BLENKINSOP, in response, remarked that there was very little for him to say, because his paper had been discussed from only one point of view, that of the cruelty cases in the police courts. He thought it was unfortunate that in these cruelty cases so much depended on a conviction, but, nevertheless, when a professional man went into court to give expert evidence and gave evidence which was not true, some disciplinary action should be taken by their College.

He did not think it right that they should allow the system to go unchallenged of veterinary surgeons being employed on, and taking up one side of a case and working it up as if they were solicitors or barristers. It was not professional, neither was it expert evidence. Expert evidence should be the honest opinion of a professional man on subjects regarding which he had been educated to form an opinion. It should not be what would suit a client, nor what would enable a client to win the case. In fact they should not talk about their case or their client.

He understood that the Inspectors of the R.S.P.C.A. obtained credit for the number of successful prosecutions which they brought. If this was so, he thought it was a great pity, because it tended to encourage the working up of cases in order to tot up the number of successful cases at the end of the year. He did not wish to say anything in disparagement of the Royal Society for the Prevention of Cruelty to Animals. The Society undoubtedly did incalculable good in safeguarding animals from cruelty, but he could not get away from the feeling that they were using as inspectors men who were not always sufficiently educated in the subjects required to carry on to the best advantage the work of the Society. (Hear, hear).

Personally he thought there was no doubt that the disputes over lameness in cruelty cases would gradually become less frequent as motor traction drove the trotting horse off the roads, because, as a rule, the slow-moving horse was not so often unfitted for work by lameness as the trotting horse.

With regard to the point mentioned by Mr. Hunting, disputes as to whether a horse had ringbone, or one disease or another, he thought the whole of these cases would be simplified, as he had suggested in his paper, by an accepted scientific nomenclature. Let them abstain from talking about a symptom as if it was a particular disease. Veterinary surgeons too frequently, he was afraid, spoke of the symptoms and not of the disease which gave rise to them.

Reference has been made to the question of working horses which were slightly lame. They must not think

for one moment from what he was going to say that he considered a horse which was suffering pain might be worked, but was there not another standpoint from which they should look at these cases, and that was from the point of view of the horse. If a horse could not be worked it was generally shot. Now, if every man who was slightly lame was asked if he would work or be shot, undoubtedly they all would prefer to work (Laughter). In the same way the horse might prefer to work. It was a very difficult problem—that of destroying life unnecessarily. They should not allow the suggestion to go forth that they countenanced the working of lame horses, but at the same time there were certain alterations in the action of horses, which, though considered technically as lameness, did not in practice prevent animals working without discomfort or pain. He was quite certain the horses to which he referred did not suffer the discomfort which many imagined. On the other hand, they frequently saw lame horses worked by people who would be the last men in the world to work them if they thought they were causing the slightest cruelty. This was very often the result of ignorance. Too much was left in the hands of the groom, and too little was known about the animal by its owner.

He had a number of letters from veterinary surgeons practising in the South of England, bearing on the subject of his paper. One of these gentlemen wrote that there are always three classes of witnesses to reckon with in Law Courts, and defined them as the witness to facts, the expert witness, and the liar. The expert witness might come very near drifting into the third class if he was not very careful how he expressed his opinion.

He considered there was a want of dignity on the part of any veterinary surgeon who took up cases to obtain convictions on technical quibbles. If men lost their professional status by acting in this way they lost nothing more than they had laid themselves out to lose (Applause).

On the proposition of the Chairman, seconded by Mr. Della Gana, a hearty vote of thanks was passed to Col. Blenkinsop for his very interesting paper, and Colonel Blenkinsop briefly acknowledged this compliment.

Mr. BURT proposed the customary vote of thanks to the Chairman for presiding. This was seconded by Mr. Lockwood and carried, and the proceedings then terminated.

THE ANNUAL DINNER.

In the evening the members dined together in an adjoining room, the Chair on this occasion being taken by Mr. Walter Burt.

At the conclusion of the repast the loyal toast of "The King" was submitted from the Chair and duly honoured.

Mr. E. WHITLEY BAKER proposed "Our Guests." It gave him a special pleasure to propose this toast that evening because they had among them as one of their guests a gentleman whom he knew several years ago as a fellow student. He referred to Colonel Blenkinsop. (Applause.) He knew the good work Col. Blenkinsop did in his student days and how well he always conducted himself, and he had since entered the Army, where he had risen, and he had also attained the D.S.O. That spoke for itself. (Applause.) Col. Blenkinsop had that afternoon placed them, as a Society, under a special debt of gratitude by contributing one of the most useful papers they had ever had placed before them. (Applause.) He assured Colonel Blenkinsop that they welcomed him amongst them, they hoped this was only the first of many occasions on which they would meet, and they wished him with all heartiness every possible success and happiness in the future. (Applause.)

Colonel BLENKINSOP, in returning thanks on behalf of the guests, remarked that as far as he personally was concerned it was very difficult to say how grateful one

really was. There were many things one looked back to as time went on, but there were probably few things one looked back to with greater pleasure than the good times they had when they were students. They met men and learnt to appreciate them in a way one rarely did in after life. As an Army man he would like to ask them to help the Army, and there were one or two ways in which they could easily do this. All veterinary surgeons were sportsmen, and as sportsmen he felt certain their profession would not allow the regular Army Veterinary Corps to go into the field in war time without the assistance which it would then require. But to render this assistance they must have training, and the only time when they could train was in the time of peace. The profession could train itself to assist its country in the time of war in two or three ways: first by letting the younger members join the Special Reserve of the Army Veterinary Corps; secondly, the middle aged men could join the Army Veterinary Corps Territorial Force; and thirdly, the older men could register their names for giving assistance in the event of that assistance being required. He wished particularly to appeal to those of them who were senior practitioners to persuade and offer facilities for the younger men to join the Special Reserve of the Army Veterinary Corps. The Territorial Force also required recruits. They found it very difficult to get the right class of men to come forward, and if they could assist in persuading the younger members to join they would be rendering a real service to their country. If they could not do either of these things, whatever they did, don't let them sneer at the men who were trying to do their duty. (Applause.) He thanked them very much for the kind way in which they had drunk the health of their guests, and, personally, he could not adequately express his gratitude. (Applause.)

Mr. BROOKMAN, who was entrusted with the toast of "Continued success to the S.C.V.S.," remarked that his first acquaintance with the Society only dated back to last September when he went to Aldershot and had a very enjoyable afternoon, and incidentally met a good many of their members. He could only say that he wished them every possible success. He was told they had eighty members, but the number should be larger seeing that they covered five counties—Surrey, Sussex, Kent, Hampshire, and Dorset—and he hoped the time would come when they would be able to boast several more members. (App.) While wishing the Society every success, which he thought they deserved, he desired to couple with the toast the name of one of their Vice-Presidents, Mr. Slocock, of Hounslow. (App.)

Mr. SLOCOCK, in reply, said he did not know what he could say for their Society except that he believed it was one of the best Societies going. (App.) It was a Society in which the members seemed to combine and pull together better than in almost any other Society he knew of. Possibly the members lived in a happier part of the world. Unhappily he was not located in one of these favoured districts, but in the poor county of Middlesex, where one had to struggle hard to get a living. Still, he was very glad to come to their gatherings, and he often wondered how it was they did not get a larger attendance of members. He thought one of the happiest and most pleasant meetings he had ever attended in the way of a small Society was their last meeting at Aldershot, when their friends of the Army Veterinary Department entertained them and enlightened them on many subjects. He did not think a body of ordinary practitioners could have met together for a day's outing and had such a mental treat as they had at Aldershot: there were so many little things and methods adopted at the Army Veterinary School that appealed to them as practitioners, and he believed when the time came for them to pay another visit they would see quite a large attendance. (App.) He had to thank

Mr. Brookman for the kind way in which he had proposed success to the Southern Counties Veterinary Society, and he was sure it was the wish of them all that both he and their other visitors would meet frequently amongst them. (App.)

Mr. DELLA GANA gave the health of "The Chairman." They all knew what Mr. Walter Burt had done for their Society in the past, and they also appreciated what he had done for the profession generally as a member of the Council. They were sorry indeed that he was no longer a member of that body, but he had not been bowled out—only stumped, and they looked forward to the time when he would go in again and do equally good work. (App.)

The CHAIRMAN, in reply, remarked that it was a very pleasant duty to have to return thanks. Mr. Della Gana had said one or two nice things about him which were perhaps more pleasant than true, but he preferred to believe they were just as true as pleasant. It was always a pleasure to come to the meetings of their Society because one felt he was meeting friends. He wished it were possible for every veterinary surgeon to be the friend of his fellow practitioner. At present it was not so in many cases, but it would be much better if it were so. (App.) They had decided that afternoon to hold their next meeting at Brighton, and he could only say that those of them who lived at Brighton would do their best to make that meeting a successful one. He also hoped that their President, Mr. Hunting, would be able to attend. (App.)

J. ALEX. TODD, Hon. Sec.

A VETERINARY ASSOCIATION FOR CONNAUGHT.

In response to a circular sent to the veterinary surgeons of Connaught, a meeting was held at Claremorris on Dec. 11th to consider the advisability of forming an Association for the Province of Connaught.

There were present: Messrs. D. Hamilton, Ballina; J. J. Vahey, Sligo; A. J. Moffett, Galway; P. F. MacCormack, Castlebar; J. C. Doran, Castlereagh; T. J. Flynn, Ballyhaunis; A. F. O'Dea, Tuam; and W. Ash-King, Claremorris.

Letters regretting inability to attend but sympathising strongly with the object of the meeting, were received from Messrs. J. J. O'Brien, Belmullet; E. A. Ryan, Strokestown; J. C. MacKittrick, Clifden, and P. M. McDonnell, Westport.

Mr. HAMILTON, who was elected chairman of the Meeting, in proposing the formation of an Association for Connaught, said that there were a number of young veterinary surgeons situated in different parts of the province who would feel the necessity of such an Association in which they could discuss matters of veterinary interest, and to which they could bring their grievances and obtain the support of the Association in obtaining their just rights. It was felt that the meetings of other Associations in Ireland were held at too great a distance for the majority of those residing in Connaught to attend without entailing great loss of time and some expense.

Mr. MACCORMACK seconded the resolution, which was carried unanimously.

The meeting then proceeded to elect officers for the year.

President. Mr. D. Hamilton, Ballina.

Vice-President. Mr. J. J. Vahey, Sligo.

Hon. Secretary and Treasurer. Mr. A. J. Moffett, Galway.

Committee. Messrs. Flynn, E. A. Ryan, J. C. Doran, and P. F. MacCormack.

The drawing up of rules was left to the Committee and to be discussed at the next meeting.

Milk Supply of Ireland Committee. The subject of giving evidence before this Committee was considered, and it was decided that the local veterinary surgeons give evidence at each centre where the Committee held enquiry.

Inspectorships under the Dairies and Cowsheds Order, 1908. After discussion it was resolved that the Local Government Board be asked not to sanction any lay inspector appointed by the District Councils when a qualified veterinary surgeon applied for the position.

Lectures to Agricultural Classes on Veterinary Hygiene. After some discussion as to the amount of the fee to be accepted for lecturing to these classes, it was agreed that a sum not less than two guineas per lecture be accepted.

It was decided that the next meeting be held at Claremorris on January 25th, 1912.

After a vote of thanks to the President for acting as such an efficient Chairman, a very successful meeting came to a close, and all the members adjourned to a substantial lunch.

A. J. MOFFETT, Hon. Sec. and Treas.

A CORRECTION.

Dear Sir,—Will you note an error which occurred in the report of meeting of the South Durham and North Yorkshire Association in *The Veterinary Record* of December 16th. Mr. Walker is there stated to have used Nuclein in a heifer which had a temperature of 102 for a fortnight, and the temperature remained stationary. The temperature of the heifer was stated by Mr. Walker to be 107.—Yours truly,

JAMES H. TAYLOR, Hon. Sec.

Royal College of Veterinary Surgeons.

EXAMINATIONS IN LONDON.

At a meeting of the Board of Examiners held in London on December 8th for the Written, and on December 15th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:

Mr. C. Holland *	Mr. H. Stephenson
E. J. Laine	B. M. R. West
C. W. Perrin	

The following passed their Third Examination:

Mr. S. E. Hill *	Mr. W. E. Petty
C. J. R. Lawrence	E. M. Robinson *
R. A. Murless	S. L. Slocock
W. F. Poulton	P. L. Thierry
A. A. Pryer *	G. M. Vincent

The following passed their Second Examination:

Mr. A. H. Adams *	Mr. B. J. W. Nicholas
W. P. S. Edwards	R. J. Stow
J. M. Knighton	R. H. Stalker
H. A. King	H. B. Williams
R. H. C. Lucas	H. S. Wright
G. F. Marais	

The following passed their First Examination:

Mr. J. Daly *	Mr. J. H. Stewart *
E. W. Garry	G. Simons *
W. Shipley	K. S. Simpson

Marked thus * passed with Second Class Honours.

EXAMINATIONS IN GLASGOW.

At a meeting of the Board of Examiners held in Glasgow on December 8th for the Written, and on December 13th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:

Mr. J. Scott	Mr. J. Gibson
--------------	---------------

The following passed their Third Examination:

Mr. H. McD. Paul*	Mr. P. J. Turner
J. McL. Galloway	G. B. Cooper

The following passed their Second Examination:

Mr. W. Barr	Mr. J. D. Fulton
R. T. Smith	

Marked thus * passed with Second Class Honours.

EXAMINATIONS IN EDINBURGH.

At a meeting of the Board of Examiners held in Edinburgh on December 8th for the Written, and on December 13th for the Oral and Practical Examinations, the following gentlemen passed their Final Examination:

Mr. S. C. Currie	Mr. T. F. Sexton
J. R. Greig	G. Currey

The following passed their Third Examination:

Mr. R. L. Armour	Mr. R. E. Drennan
F. J. L. Croudace	S. E. Holmes
A. Q. Hall	D. R. Williamson
C. Nicholson	

The following passed their Second Examination:

Mr. E. Sewell	Mr. G. Williamson
J. W. Stanley	

The following passed their First Examination:

Mr. W. J. Bainbridge*	Mr. L. Littler
P. McLaughlin*	D. S. Phorson
T. M. Martin	T. A. Shaw

Marked thus * passed with Second Class Honours.

EXAMINATIONS IN DUBLIN.

At the recent examinations held in the Royal Veterinary College of Ireland, Ballsbridge, Dublin, the following gentlemen passed their Final Examination and were registered Members of the Royal College of Veterinary Surgeons:

Mr. F. J. Shearman	Mr. R. Marnier
T. L. Shea	W. J. O'Donoghue
R. P. Byrne	P. W. D. O'Connell
R. Devereux	A. O'Neill
J. J. G. Keppel	W. E. Phipps
J. T. Evans	V. Fox

The following passed their Third Examination:

Mr. M. McClancy	Mr. F. J. Carroll
J. J. O'Neill	T. F. Quirke*
W. P. Walsh	P. J. Sheil

The following passed their Second Examination:

Mr. L. A. Herbert	Mr. J. Campbell
F. D. Huston	S. O'Donel
St. J. C. P. McFarlan	M. H. Reid
J. Shannon	

The following passed their First Examination:

Mr. A. J. W. L. Birchall	Mr. J. P. Fahy
T. J. McDonald	M. J. McGing
G. McElligott	M. A. Murphy
T. O'Connor*	W. J. Ward

Marked thus * passed with Second Class Honours.

EXAMINATIONS IN LIVERPOOL.

The following gentleman passed his Second Examination:—

Mr. M. W. Holland.

The following passed their First Examination:—

Mr. S. S. Herbert	Mr. B. Whittam
-------------------	----------------

PARLIAMENTARY.

THE FINANCE BILL.

In the House of Commons, on Tuesday, Dec. 12.

This Bill was considered on Report.

Mr. SANDERSON (Cumberland, Appleby, Opp.) moved a new clause extending the allowances in respect to the duty on motor spirits, now allowed to medical practitioners, to veterinary surgeons.

Mr. C. BATHURST (Wilton, Opp.) seconded. If the Government granted the exemption, he said, it would encourage veterinary surgeons to keep motor cars, which were a great convenience in enabling prompt attention to be given to outbreaks of anthrax, foot-and-mouth disease, etc.

Mr. Sandys, Major Anstruther-Gray (St. Andrews Burghs, Opp.), and Mr. Fell (Great Yarmouth, Opp.) supported the new clause.

Mr. McKINNON WOOD regretted that the Government could not make a concession in favour of veterinary surgeons. If they did so it would open the door to still further exemptions until the loss to the revenue became serious.

Mr. AUSTEN CHAMBERLAIN (Worcestershire E., Opp.) said that this was really a special case for exemption, and he was very sorry the Government had not seen their way to meet the claims made on behalf of veterinary surgeons. He supported the clause, and maintained that it was in the public interest that this exemption should be made. Veterinary surgeons had to travel very long distances in the beneficent cause of their work among animals, and unless they could take advantage of the motor-car a hindrance would be imported into their work, an increase of unnecessary suffering imposed on animals, and a great loss caused to one of the primary industries of the country. (Hear).

Personal.

Mr. TOM VALENTINE PETTIFER, F.R.C.V.S., The Knoll, Tetbury, Veterinary Inspector of the Board of Agriculture and Fisheries, has been appointed a Justice of the Peace for Gloucestershire.

The Veterinary Committee of the R.A.S.E. has recommended that Mr. Brennan De Vine, F.R.C.V.S., R.S.S., A.F.C.L., should be asked to deliver the lecture on "The Horse's Foot" in the showyard at Doncaster, 1912.

M. LECLAINCHE, Correspondent of the Institute, Professor at the National Veterinary School at Toulouse, has been appointed Inspector General, Chief of Inspection of the Veterinary Sanitary Service.

Prof. G. BARRIER, Director of the Alfort Veterinary School, becomes Inspector General of the French Veterinary Schools in succession to Dr. Chauveau.

Prof. VALLEE has been appointed Director of the Alfort School.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*,

WAR OFFICE, WHITEHALL, Dec. 15.

REGULAR FORCES. ARMY VETERINARY CORPS.

Lieut. L. L. Dixon from the Half-pay List to be Capt., and to rank for seniority without pay and allowances from Sept. 5 (Nov. 8); the notifications in the *Gazette* of Nov. 7 and 24 are cancelled.

Maj. F. W. Wilson on arrival from India has been posted to Aldershot as Officer commanding the Army Veterinary Corps Sections at that station.

The following officers embarked on 13th December for a tour of service in India:—Maj. A. E. Clarke, Lieuts. R. F. Bett, P. D. Carey, and E. G. Turner.

Capt. K. McL. McKenzie arrived from South Africa on 14th December, and has been posted for duty at York.

Capt. H. E. Gibbs on resigning the appointment of Deputy Assistant Director-General, Army Veterinary Service, at headquarters, has been posted to Shorncliffe.

The following officers have been transferred to the stations as under:—Capt. A. Edgar from Leeds to Athlone; Lieut. W. St. J. F. McCartney from Woolwich to Bulford; Lieut. R. C. G. Thwaytes from Aldershot to Dublin; Lieuts. W. H. Thomas and G. A. Kelly from Aldershot to Woolwich.

OBITUARY.

SYDNEY SMITH, v.s., Usk, Monmouthshire, died on Dec. 17th from senile decay. Aged 82 years.

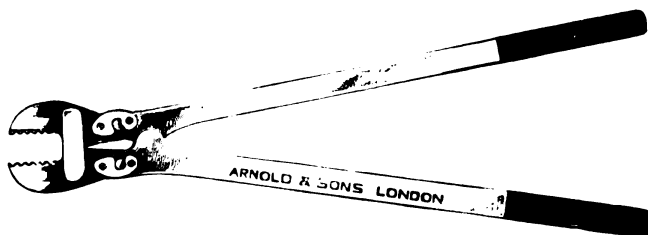

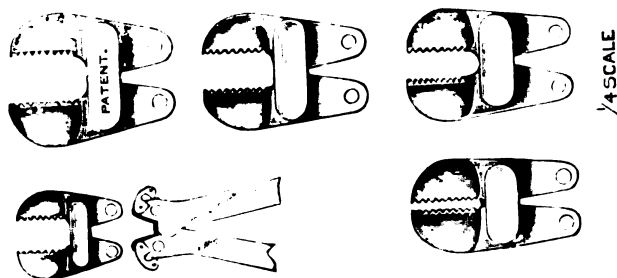

Mr. G. R. Murray, F.R.S.

The science of botany has lost a distinguished student by the death of Mr. George Robert Murray, F.R.S., who passed away at Stonehaven. Mr. Murray was born at Arbroath fifty-three years ago, and had devoted his life to botanical investigations. For some time he was Lecturer on Botany at St. George's Hospital Medical School and the Royal Veterinary College, London. In 1886 he became attached to the solar eclipse expedition to the West Indies, and about 1893 was appointed keeper of the department of botany in the British Museum. He was scientific director of the National Antarctic Expedition of 1901, and about that time became a Fellow of the Royal Society.—*The Daily Telegraph*.

PRACTICES FOR DISPOSAL

PURCHASERS ARE REQUESTED to call, or write stating their requirements, as we have numerous Practices on our Register which have not been advertised. *No charge* is made to purchasers.

To Vendors.

WE make *no charge* unless a Sale is effected. If you have a genuine Practice you wish to sell quickly and without publicity we shall be pleased to place particulars on our Register.

PROSPECTUS, containing "*Hints to Vendors*" and "*Hints to Purchasers*," post free on application.

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

As Locum

EXPERIENCED M.R.C.V.S., will act as locum, town or country practice. Free Dec. 30th. Address, J. B. Taylor, M.R.C.V.S., Shawlands House, by Larkhall, Lanarkshire.

As Assistant

UNQUALIFIED assistant, son of V.S., aged 26 desires post in good mixed town and country practice, permanency if possible. Energetic, good dispenser and book-keeper, and well up in all branches: ride, drive and cycle. Excellent references: previous situation 18 months, disengaged 31st Dec. Address, 4123 V.R., 20 Fulham Road, London, S.W.

For Sale

HIGH-CLASS, old established, suburban practice, mixed (chiefly dog), in good neighbourhood: held on lease: brick built kennels. Price £300, to include drugs, instruments and fittings. Well stocked surgery, good introduction, owner retiring. Bargain. Address, 3125 V.R., 20 Fulham Road, London, S.W.

As Locum or Assistant

FINAL year student (29) offers services. Sound experience in town and country practice: Ride and drive horse or car. Free Dec. 15th. S. H. L. Woods, R. V. Coll., Camden Town, N.W.

Assistant Wanted

FOR country practice, must be able to do standing operation, and well up in cattle practice. State age, references. Sign bond. Address, 3121 V.R. 20 Fulham Road, London, S.W.

Practice or Partnership

ADVERTISER, who has £1200 on hand, will be pleased to have particulars of practice or partnership for sale up to that amount, confidence respected, no intermediaries. Address, 2114 V.R., 20 Fulham Road London, S.W.

Replies to Numbered Advertisements

WHEN replies to several of these advertisements are sent to this office at one despatch, it is not necessary that they should be stamped separately: they may be enclosed in one envelope, but should be marked outside "Replies."

News Cuttings.

SCRAPS which cannot readily be authenticated either as to origin or date, frequently give unnecessary trouble. A convenient method is to send the page of the newspaper containing the marked paragraph in an unsealed envelope. Postage $\frac{1}{2}$ d.

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Gregg's Tracheotomy Tube

MADE in one piece (improved hinged flanges.) The best and the cheapest Tube on the Market. Used by all up-to-date Veterinary Surgeons. Satisfaction guaranteed. Price 15/- Robertson & Co., Victoria Square, Belfast.

CHEAP BOTTLES.

A large quantity of named medical bottles (these have various chemists' names on and washed ready for use)
2oz., 3oz., 4oz., 6oz. and 8oz. at 5/6 a gross.
10oz., 12oz., and 16oz. at 7/- a gross.
Cash with order. Carriage paid on £3 orders within 70 miles, and on £5 orders any distance.
Other bottles and jars quoted for.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1225.

DECEMBER 30, 1911.

VOL. XXIV.

VETERINARY EVIDENCE.

Col. Blenkinsop's recent paper upon this subject will probably cause a little discussion, and is certain to be widely read and pondered. It is an able and impartial survey of a subject replete with difficulties and pitfalls: and while it can initiate no radical reform, its perusal and consideration must do some good.

Of course, expert evidence in veterinary as in most other technical matters will always be a source of difficulty. However scrupulous professional witnesses may be, differences of opinion will always be common, and lawyers will accentuate them. But perhaps no professional function is so conducive to the gradual abandonment of scruple as the giving of expert evidence. A few good general rules of conduct for the guidance of expert witnesses may be laid down, as has been done by Col. Blenkinsop. But the difficulty lies in the practical application of such rules to the ever-varying conditions of individual cases, in the face of lawyers and clients who, of course, desire professional evidence as favourable to their side as possible. The last-named point forms the great temptation to professional witnesses to stray from the path of strict rectitude. Under its influence, very many men depart a little from scrupulous fairness, and some develop into perjurers.

Undoubtedly the present state of affairs is capable of improvement, though we do not think that matters are a whit worse within our profession than amongst medical men. But improvement is most likely to come very slowly, by a gradual education of the profession and the public alike. Many laymen do not yet understand how inexact and debatable a subject medicine is, and with a growing popular enlightenment in this respect, the dogmatic expert witness will become less in demand. Many professional men, also, do not fully appreciate the high responsibilities attached to the giving of technical evidence, and such papers as this of Colonel Blenkinsop's cannot fail to raise the ideals of a few. Men will read it, and call to mind cases in which, without conscious dishonesty, they have deviated a little from the strict code which should be observed by the professional witness—and some will do so less frequently in the future.

THE END OF THE YEAR.

Again, at this season, we tender all our readers our best wishes for the year to come. The year just ending has been quiet for the profession, and very anxious for the Body Corporate, and in the latter particular the coming year bids fair to be likewise. Nevertheless, there is a chance that 1912 will see the financial stability of the Royal College assured, and in that hope we say good-bye to 1911.

TUBERCULOSIS IN THE DOG. ✓

By E. WALLIS HOARE, F.R.C.V.S.

Subject. An Irish terrier dog, aged 15 months.

History. The animal when purchased by the present owner in January, 1911, was five months old. At that time he was in poor condition and looked unhealthy, but with good care and liberal feeding he commenced to improve slowly; he had a slight cough for about two months, but after this period got into good condition, and continued so until the last ten days of October. Then he showed evidences of illness, such as a capricious appetite, dull expression of countenance, and accelerated respirations; no cough was present, but the animal rapidly lost condition.

After showing the above symptoms for about ten days, he was sent to my infirmary on Nov. 1st, for treatment, and the following symptoms were observed. Condition poor, but no emaciation present; respirations accelerated, marked heaving of the flanks, and abdominal breathing, sad expression of countenance; the head and neck were carried in a stiff manner.

Physical signs. Right side—percussion showed complete dullness of a wooden character, and on auscultation there was an entire absence of the respiratory sounds. On the left side these conditions were also present, but far less marked. The cardiac sounds were rather indistinct and the cardiac impulse weak. Evidences of a slight degree of ascites were also present. No cough and no nasal discharge.

Diagnosis. Pleurisy with pleural effusion, probably tubercular.

While in the infirmary the dog seemed to improve and fed fairly well, in fact the owner was anxious to take him home, but I suggested the employment of the tuberculin test. However, the animal died during the night of Nov. 6.

Autopsy. The right side of the thorax contained an enormous amount of fluid of a light greenish tint, the mediastinum was fixed towards the left side; the right lung was pressed up to the vertebral column and completely collapsed. The left side contained a smaller amount of fluid. The costal pleura of both sides was inflamed, and showed very small tubercles, especially close to the sternal region. No organized lymph was present, and no adhesions. The abdominal cavity contained a small amount of effusion, but no other lesions were detected.

I forwarded the lungs and heart to Prof. Woolbridge, Royal Veterinary College, London, who kindly examined them and reported as follows:—

"The right lung was completely collapsed, and the pleura inflamed and covered by a croupous deposit. The left lung was collapsed along its lower edges only. The lymphatic glands of the chest were slightly enlarged and juicy, but showed no other changes. The left bronchial tubes were filled with a sticky, frothy exudate, which contained numerous free tubercle bacilli, as shown on microscopic examination and staining with Ziehl-Neelsen."

Remarks.—As is often the case with canine tuberculosis, symptoms were not present—or not observed—until the disease was far advanced. This dog was about nine months in his owner's possession, and beyond the slight signs of illness manifested during the first two months, nothing wrong was detected until five months afterwards. The animal was kept in the house and was made a pet of by children, but no suspicion of any danger existed.

This has been the usual history of such cases, but in the present instance the dog was young—only 15 months of age.

It is very probable that if post-mortem examinations were more regularly carried out, cases of canine tuberculosis would be found to be more common than is at present imagined. Unfortunately it is not always possible to obtain permission from the owners to make autopsies, and thus much valuable material is lost. Some will even object to the tuberculin test being carried out, although the importance of a correct diagnosis has been pointed out to them. Others, again, do not believe that tuberculosis occurs in the dog, and this erroneous view is fostered by the opinion expressed by some veterinary surgeons in connection with the subject.

CENTRAL VETERINARY SOCIETY.

An ordinary general meeting was held at 10 Red Lion Square, on Thursday, December 7th, Mr. R. J. Foreman, President, in the chair. The following Fellows signed the attendance book: Messrs. J. W. McIntosh, W. R. Davis, D. Stewart, P. W. Dayer Smith, R. Bryden, A. Gordon, J. F. Macdonald, E. Lionel Stroud, W. Perryman, A. Neish, G. H. Livesey, A. L. Butters, W. S. Mulvey, R. A. Philp, James Rowe, James A. Gosling, Wm. Willis, Herbert King, J. J. Kelly, Wm. L. Harrison, Sidney Villar, Profs. H. A. Woodruff, G. H. Wooldridge.

Visitors: Messrs. K. Davis, H. J. Hare, D. Blyth, and S. H. L. Woods.

On the motion of Mr. Stroud, seconded by Mr. P. Dayer Smith, the minutes of the last meeting were taken as read and confirmed.

CORRESPONDENCE.

The following letters were read:

Regret for inability to attend the meeting from Mr. James T. Angwin and Mr. W. Shipley.

Resignation from Mr. R. Porch and Lieut.-Colonel R. Moore.

From Mr. J. B. A. Hare stating in reply to a letter from the Secretary asking him to reconsider his resignation, that he adhered to his decision.

From Mr. Ainsworth Wilson deciding to continue being a Fellow.

From Capt. S. F. G. Pallin resigning his Fellowship

on account of being away for five years on active service.

From Mr. Alfred Prudames acknowledging the letter which the Secretary had been authorised to write to him on his resignation.

From Mr. G. J. Bell explaining that on account of his wife's illness he had been unable to attend the Congress at Belfast, and hoping that that had not caused the Society any inconvenience.

From Prof. Gofton, Hon. Sec. of the Amalgamation Committee, asking formal approval of the scheme.

From Mr. A. M. Trotter, *re* the Association of Veterinary Officers of Health.

The Hon. Sec. (Mr. Hugh A. MacCormack) stated that he had written on his own responsibility to Capt. Pallin explaining that while Fellows were on active service they became Honorary Fellows, and that on his return he would be placed on the full register.

The PRESIDENT said the Secretary had done perfectly right in replying to Capt. Pallin as he had done.

On the motion of Prof. Wooldridge, seconded by Mr. Davis, it was resolved that letters regretting resignation should be written by the Secretary to Mr. Porch and Lieut.-Col. Moore.

On the motion of Prof. Wooldridge, Prof. Gofton's letter was referred to the next meeting.

The PRESIDENT said the matter referred to by Mr. Trotter in regard to the Association of Veterinary Officers of Health had evidently been studied by a very strong board, and he thought they could not do better than agree to it.

Professor WOOLDRIDGE proposed, and Mr. Butters seconded, a resolution that the action of the Association of Veterinary Officers of Health should be supported.

The PRESIDENT asked if it were the wish of the meeting that the resolutions sent in by Mr. Trotter, as representing the Association, should be agreed to.

Prof. WOOLDRIDGE thought that as the resolutions asked for a great deal, the Society ought to be careful in wording its support.

Mr. BUTTERS said they might express approval of any scheme which would produce a pure milk supply and control tuberculosis.

Prof. WOOLDRIDGE moved: "That the Central Veterinary Society expresses sympathy with the action of the Association of Veterinary Officers of Health in their endeavour to obtain legislation for the control of tuberculosis and other diseases of cattle, and to obtain a pure milk supply."

The PRESIDENT agreed with the Resolution, as that would not commit them to anything at all.

Prof. WOOLDRUFF said that while he agreed with the resolution, it seemed to him that it was necessary to go a stage further. While sympathy with their colleagues was all very well, that sympathy might take a more practical form by urging the authorities which had power to act to do so. Pious opinions of sympathy were not much good at this time of day, and if they had not time adequately to discuss the question that evening he thought it should be put down on the agenda of another meeting later on in the session for a proper discussion. Such an important Society as theirs, the metropolitan Society, should take a lead in the subject, and not merely pass a pious resolution. The Association of Veterinary Officers of Health would be satisfied if the Society said they sympathised with them and were going to do their part to urge on the same programme.

Mr. MULVEY thought that they should surely discuss anything before sympathising or disagreeing with it.

Prof. WOOLDRIDGE suggested that such an expression of sympathy should be given as would not prevent the Central Veterinary Society from going into the question thoroughly.

Prof. Wooldridge's motion was agreed to.

Mr. MULVEY then moved that the subject be put on the agenda of a future meeting, to be held at an early date.

Mr. PHILP seconded the motion, which was agreed to.

Prof. WOOLDRIDGE suggested that Mr. Mulvey should himself bring it forward. That was obviously the right thing to do.

ELECTION OF FELLOWS.

The PRESIDENT announced that the following had been unanimously elected: Mr. J. W. SUGDEN, M.R.C.V.S., Southminster, Mr. J. A. GOSLING, M.R.C.V.S., 212 Goswell Road, E.C., Mr. C. A. W. CUNNINGHAM, M.R.C.V.S., 128 Goswell Road, E.C., and Mr. T. A. B. COCKSEGE, M.R.C.V.S., Emsworth, Hants.

PRESIDENTIAL ADDRESS.

R. J. FOREMAN, M.R.C.V.S.

Gentlemen,—There is one privilege the Presidentship of this Society carries with it that I appreciate—there is no discussion on this address. I think it would be a most happy position for a "cynic" to air his views from.

I would rather have been excused from inflicting this address upon you, but am told that custom cannot be altered to suit me, so here are a few of my impressions on subjects interesting to the profession at present.

I hope the time is close at hand when the Veterinary Amendment Bill will assist the Royal College of Veterinary Surgeons out of its difficulties. I think that a sufficient sum of money should be obtained from the annual fee to place the R.C.V.S. on a sound financial basis, but there ought not to be a prodigal balance to tempt a lavish expenditure at the expense of the general practitioner. When the "house is in order" the interests of the general practitioner, as being the main provider of the funds, should be the first consideration. Let him be protected to the utmost, especially against quacks, patent medicine vendors, not only through prosecutions where possible, but by finding some means of showing the public the folly of trusting to the much-advertised nostrums. We know that each practitioner does this in his own way amongst his clients, but such teaching takes a very long time to travel round. Surely something of the kind, undertaken by *The British Medical Journal* in their publication "Secret Remedies" could be done, and if written in a racy style it would sell like hot cakes, and more than pay for the expense. There have not been any libel actions against the *B.M.J.* that I have heard of, and I do not think we would need fear any. If this or some other scheme succeeded, I am sure not a G.P. would begrudge an annual fee of one, or even two, guineas, for he would be enabled to view the onslaught of motors with equanimity for a few more years.

There is a hardship which the publicity given to the Amended Bill has brought about; very many more "empirics" have started all over the country. Five or six unqualified men have set up in a district not very far from mine, and I have heard of other instances but not in such a wholesale style.

We ought to keep on agitating for the rebate on the Petrol Tax. It is a big item where 20,000 miles per annum are covered, and I have no doubt many motor-ing V.S.'s do that or more.

Then there is the action over the crest of the R.C.V.S. In some districts the crest is looked upon with great awe by clients, who would not think they were getting a proper powder or drench unless the label had the "picture" on it. In other more advanced districts, and especially amongst the business firms, it is probably never noticed, the M.R.C.V.S. being quite sufficient for them. In the old days, before education became so general, I think it was quite a necessity, but now that the term veterinary surgeon is more commonly used and understood than the old term "farrier," it is not so much needed. I think it is entirely a matter of individual preference

depending on the district. I use it on colic draughts to enable the public to more easily distinguish them from the ones sold by quacks, but if it is decided that we each have to pay the tax when using the crest I do not think the Exchequer will benefit through me. I do think a fee paid by the R.C.V.S. ought to cover us all in its use.

In looking over the swine fever returns it struck me that, in comparison with the total value of the three million swine in the kingdom, an enormous sum of money is being spent in trying to stamp the disease out, and up to now the attempt is a failure. It is time the "Powers that be" remembered the services of the general practitioners during the pleuro-pneumonia outbreak, and made use of them again to the same extent. We could do with some of the money now being wasted and give good value for it.

It will be a good day for the veterinary profession when the R.C.V.S. grants a diploma for a "Veterinary Department of Public Health," and as things are progressing in the mechanical world, the sooner the better. Such a degree would quickly receive recognition. It is no use waiting for it to be demanded from us, far better to have it ready, even if it has to be stored away for a time in a bottom drawer.

Has it struck any of you how the much discussed Insurance Bill will affect us. I will mention one point which, if a fact, will cause us a little amusement, or otherwise, each time it occurs.

Suppose I wish to operate on two days in one week. Having only one man regularly employed I send him on to the highway to get help. After a weary pilgrimage and much persuasion he inveigles three "unemployed workmen" to come and pull on a rope. I have to enquire of each man if he has earned 9s. and had his insurance paid for the week. Next day the same procedure with three different men. If the six have not been employed to the extent of the 9s., and my payment brings their earnings over that sum, I have to pay 1 6 in addition to what I usually give them, and I have to be a kind of a stamp office as well, for I suppose I shall have to go through the same performance each time I get a man to hold my horse. If I don't, and he gives me away, the fine will add to the fun of the thing. I may have misread the clause, but that is how I interpret it.

I have wondered if there will be any advantage to us as a profession through the treatment coming into fashion in human medicine. I mean "Organo therapy." It seems to be founded upon the old Indian habit of eating those parts of their fallen foes they thought themselves deficient in—heart for courage, testicles for potency, etc. The treatment is gaining ground and may take the place of drugs to a great extent; but the progress is slow, as only little work is being done in research by just a few very interested men. We might look into it and give data as to the special periods in the lives of animals when the value of the glands, blood and milk, is at its height; and also experiment in the improvement of animals so as to produce more active glands for any special purpose.

In conclusion, just a few words about ourselves. We have done well in the past and ought to live *up to* our reputation and not *on it*. There is a tendency to get slack and think "Oh, if I don't write a paper some one else will"; but if we are all thinking alike we come to a standstill. Perhaps we are not all capable of giving a paper, but each can join in the discussion or bring an interesting specimen. These three things are essential for the Society's existence.

As a change, occasionally a Fellow ought to be courageous and tell us of a dismal failure or two. It is very soothing to other Fellows to know that they are not the only ones who make mistakes, and much is to be learned through the failures, as well as successes of others.

I again thank all the Fellows of the Society for the

honour conferred upon me, and I hope to find from your continued support that you have not repented your choice.

CONGRESS OF THE ROYAL INSTITUTE OF PUBLIC HEALTH
DELEGATE'S REPORT.

Mr. President and Gentlemen,—On Tuesday, August 15th, the Royal Institute of Public Health held in Trinity College, Dublin, its third annual Congress in that city.

The programme informed us that the first Annual Congress ever held of the then British—now the Royal—Institute of Public Health took place in Dublin on August 17th, 18th, 19th, and 20th, 1892.

The programme also made the interesting statement that Dublin University was the first of the Universities in the United Kingdom to recognise the growing importance, which the Public Health question was assuming, and in 1875 instituted a special examination in State Medicine.

It would appear, therefore, quite in the fitness of things, that the Congress of the Royal Institute of Public Health should have found a resting place within the staid and sober walls of this historic and famous seat of learning.

We are told it was a custom much in vogue amongst the early Greeks, when the Elders assembled to discuss any great and pressing question of social or political reform, to meet in the open air, as they held that their deliberations were not assisted by architectural grandeur, but rather hindered by it. They maintained that "men's heads were thereby filled by 'vain and improbable fancies' when they were assembled for debate in places where they could see statuary and paintings, or the richly ornamental roof of the Council Chamber." I am not going to offer any opinion, or call in question the wisdom of the Greeks in arranging their business in their own way, but such ideas can scarcely be said to fit in with our modern views on suggestion and environment. We know the Greeks were an impressionable people, a lusty and energetic race, and probably the Elders were right, and considered it safer to keep them in the open, as they knew their bodies were as prone to sudden expansion as their minds, and during the process they would be found no respecters of persons or objects of high art.

He, however, would be a sorry jade indeed, who would sit unconcerned midst such surroundings as those of Trinity College, Dublin. To an Irishman especially who knows anything of the striking part this Institution has played in the intellectual life of the Nation, Old Trinity has, and will continue to have, a proud and abiding interest. Its intellectual history is inseparably bound up with and hallowed by the memories of men whose learning was as broad and general as the casing air, and so profound that their names and their teachings have penetrated to the uttermost ends of the earth. Beneath the shadows of those austere and gloomy walls have walked, obscure and alone, some of the brightest intellects that yet illumine and adorn the pages of English literature. Old Trinity has more than justified her existence; she is still instinct with an unfading spirit of youth; with posterity her place is secure. She has nurtured, matured, and inspired by her teachings some of the broadest and most fruitful minds that have ever—whether in the field or in the Senate—helped to shape the destinies of this mighty Empire.

It is curious to reflect that in a nation, which, from one period of its history to another, has been rent asunder, and torn with political or social strife, Trinity College has kept steadily burning the lamp of learning, and has sent out into the world men skilled in almost every branch of human knowledge. It would be unnecessary as well as difficult for me to touch on even the fringe of the subject, or pass in review the phalanx of

intellectual giants who have carried her name and her fame throughout the English speaking world.

She has given to medicine and surgery such distinguished names as Crampton, Collis, Butcher and Corrigan. To the practice of the law she has given such distinguished ornaments as Curran, Brewster, Bushe, Dowse, Whiteside, McDonagh, Pallas, Armstrong, and Isaac Butt—men whose wit, eloquence, and profound knowledge of the law maintained at its highest the already high traditions of the Irish Bar. To the realms of politics she has given Edmund Burke, Grattan, Plunkett and Flood. To dramatic literature she has given such imperishable names as Congreve, Masklin, Goldsmith and Sheridan—men whose works age cannot wither, nor custom stale their infinite variety; they are as fresh and invigorating, and as full of human interest to-day as the day they were written, and will in all probability endure as long as the English language continues to be the medium by which men communicate their ideas. In our own day may be mentioned such ripe scholars as Lecky, Ingram, Galbraith, Haughton, Mahaffy, and Ball.

The position of Trinity College, viewed from the standpoint of history, is unique and remarkable. She has never been at any period of her history, either in the spirit or the letter, national, or an expression of the spirit of the nation. She has held aloof from all national sentiment, or anything that would characterise her as truly racy of the soil. She has always been sternly on the side of the Constitution. She has maintained a chilly indifference to the moving aspirations of the times, and she remains to-day as much apart from the people as ever she was. She has remained almost impassive and apparently indifferent to the recent stormy period through which the education question has passed in Ireland, and which has culminated in the creation of a National University. Yet, strange as all that may appear, the fire of revolution has been kindled and kept alive in her very heart. A body of men have from time to time found their way within her walls in whom the spirit of revolt and revolution was the all-inspiring motive of their lives, and whose acts have at times done much to shake and thwart the power of the English Government in Ireland. Foremost amongst these might be mentioned Lord Edward FitzGerald, and Robert Emmett—men who, however mistaken their motives have been, have laid down everything—even their lives—in support of their convictions; and as time has mellowed their memories, and softened the feelings of those who disapprove of their opinions and condemned their methods, yet there is to-day a large body of Irishmen in Ireland and elsewhere of all shades of political and religious thought who do not hesitate to point to them as types of the purest and the noblest spirits that ever flew in the face of oppression, or sanctified with their blood the cause of human liberty in any country in the world.

Whatever may be the future history of education in Ireland, the record of Trinity College will be hard to beat, although the new National University may attract a greater number of disciples, and afford more scope and encouragement for the development of more advanced methods of thought, yet Trinity, by reason of her great traditions and intellectual associations, will always remain a source of pride and inspiration to Irishmen.

I am, however, reminded my business is to report the proceedings of the Congress of the Royal Institute of Public Health, but I may be pardoned for putting before you a few of the impressions that passed across my mind as I attended from day to day the work of the Congress.

The Congress was opened before a very distinguished assembly, under the Presidency of Lady Aberdeen, who delivered the inaugural address, in which she dwelt at considerable length on the importance of enlisting the

sympathies of women in any health movement, and pointed out the necessity of advancing the claims of women for a broader and better system of education in what she called the household sciences. She strongly maintained that whatever other branches of education claimed the attention of woman, or, however she may be turned away by side issues on public questions, the care of the household and the services of the home should always remain the primary function of woman.

The section of Comparative Pathology and Veterinary Hygiene was opened under the Presidency of Professor Mettam in the School of Pathology. The Professor opened the section by the delivery of an extremely able and interesting address, in which he dwelt at length on the question of infection as it occurred between man and animals. He said infection in the lower animals was the same, or almost the same as in man, and he maintained it was a false conception to consider man apart from the lower animals. Dealing with the question of tuberculosis, he marshalled a great variety of interesting facts in quite a masterful way. He said there appeared little doubt that infection in man was mainly from one human being to another, and the question arose how infection was handed on, and what was the portal for the introduction of the infecting agent. He did not think the respiratory tract was the channel of infection, but it was not possible to exclude infection from that source. From a wide experience he held that infection by the respiratory tract was rare, if it existed at all. He dwelt on the danger of using contaminated meat and milk—the danger from contaminated milk particularly could not be exaggerated.

The speakers were Colonel Moore, Mr. Winter, Mr. Cooney (President of the Dublin Victuallers Association) Prof. O'Connor, and Mr. Mason.

On Wednesday morning the real work of the section may be said to have commenced, when a paper was read by Professor McWeeney entitled "The Relations of the Bacilli of the Typho-coli Group to Meat Poisoning and Paratyphoid." In the course of this most interesting address the Professor said that most of the outbreaks of food poisoning hitherto recorded had been produced by the use of food that had not been in the least degree putrid. Moreover, he said, the alkaloids of putrefaction, in so far as they were poisonous at all, were quite capable of producing the symptoms recorded in carefully observed cases. In the deplorable outbreak of poisoning in Limerick recently in which so many people lost their lives, and which was traced to Gaertner's bacillus, the meat, though stale, was not complained of by those who partook of it. He had added the specific bacilli obtained in this case to a shin of cold beef, and he was astonished to observe the appalling rapidity with which it impregnated the meat without in the least interfering with its normal appearance. He strongly advocated that all killing should take place in abattoirs. All serious cases of poisoning had been traced to private slaughterhouses, and in such cases there was evidence pointing to the fact that the animal was ill, or actually dying, at the time of slaughter. In all these cases careful inspection revealed such conditions as pyæmic abscesses, umbilical infection, septic enteritis, or endometritis, more especially in wasted or emaciated animals.

Bacteriological examination was essential and should be resorted to at once in all such cases, and no properly constituted abattoir should be considered fully equipped without having been furnished with a laboratory where such investigations could be properly carried out.

A very full and interesting discussion followed, in which Sir Christopher Nixon, Professor Craig, Mr. Devine, Mr. Begg, Prof. O'Connor, Mr. Hatch (President of the Cowkeepers Association), Mr. Mason, and Mr. Cooney took part.

During the course of this discussion what appeared to me to be a rather amusing incident took place. Prof. McWeeney, as all who know him are aware, is an extremely able and highly cultured man. He has a clear fluent style, and speaks in a round voice, without a trace of any particular accent, but he has the faintest suggestion of a lisp. When Mr. Begg, a gentleman from the North with a pronounced Scotch accent, rose to contribute his portion to the discussion, he began by complaining that most of the interest of the paper was destroyed by what he called the Professor's "dialect." At this pronouncement there was some consternation, during which the learned Professor slowly elevated his gold rimmed spectacles to the bridge of his nose, and calmly contemplated, with a mixed expression, the gentlemen with the Scotch accent, who so bitterly complained of his "dialect."

Mr. Devine, F.R.C.V.S., read a clever paper on "The Contamination of Milk occurring between the cow and the consumer," in which he passed, in review, the methods adopted on the Continent in handling and preparing milk for public consumption. The paper also gave rise to a very full discussion, in which Sir Christopher Nixon, Messrs. Holland, Winter, Watson, Mason, Hatch, Cooney, and several other speakers took part.

Mr. Hatch forcibly called attention to the fact that men who, like himself, incurred considerable expense at intervals in having their dairy cows tested, and who embrace every modern idea that made for improvement in the conditions of handling and keeping milk, received no recognition from the public, beyond the man who complied only with those conditions which barely kept him within the law. He pressed strongly the point that those members of the medical profession who had the power should take this matter up and insist, wherever they could exercise that power, that men who were progressive in their methods, if not getting actually the preference, should be given at least proper recognition and encouragement.

On Thursday, Prof. Craig read a paper, which exhibited evidence of great care and labour in its preparation, on the "Diseases communicable from animals to man," and in the course of which he dwelt at considerable length on the numerous ways in which disease is transmitted, and pointed out how prevalent tuberculosis is in dogs and cats, and cited cases in which diseases had been communicated to man by pigeons.

Speaking to a vote of thanks to Prof. Craig, Mr. T. W. Russell, M.P., Vice-President of the Department of Agriculture, delivered himself of a very significant speech, in the course of which he dealt with the recent outbreak of anthrax in the County Wexford. He said that when cases of this kind broke out, he inquired from the responsible official in the Department the cause of those outbreaks, he was told they did not know. He, however, paid a high compliment to the Irish Veterinary Department, and said it was creditable to them that for a quarter of a century they had kept the country free from foot-and-mouth disease. He deplored that at this hour of the day research work had done no more for them than to draw a cordon around an affected area, and slaughter all within it. This is a striking example of the child-like simplicity which usually pervades official utterances when they pretend to deal with a subject of a purely technical character. It never occurred to Mr. Russell to inquire how much or how little the Department, of which he is the official head, had done for the prosecution of research work in Ireland. Mr. Russell was, however, very sympathetic, and said more research work should be done, and more money should be provided for it. They had in the Department been promised considerable sums of money by the Development Committee—a Department of State which had the distribution annually of three-quarters of

a million. They had had already £100,000, and other claims were still unsatisfied. The question of research work, he said, was immediate and important—not only to find out the cause of disease, but the necessary remedies to apply to them.

The other speakers were Prof. Mettam, Col. Moore, Mr. Dunlop, Mr. Winter, and Mr. Mason.

Sir Charles Cameron read a paper entitled "Suggested amendments in laws and regulations in dealing with milk." In the course of his paper, Sir Charles referred to some recent outbreaks of fever in Dublin, where investigation showed the disease was traceable to certain affected dairies. He considered the sanitary authorities should be empowered to prohibit the sale of milk in cases in which it was found that persons using milk from those sources suffered from typhoid fever, and where no other cause could be found. He advocated that persons engaged in handling milk should be from time to time submitted to medical examination. He also advocated legislation enabling compensation to be given for cows, which in the interest of Public Health had to be slaughtered.

Dr. McGuinness, referring to the question in the course of his speech, said the sanitary laws would never be complete until they had a Minister of Public Health appointed.

After some further discussion, Mr. Mason proposed, and Mr. Howard seconded the following resolution, which was passed:—"That in the opinion of this section the appointment of a Minister of Public Health is essential for the protection of the health of the Community."

Prof. O'Connor moved, and Mr. Begg seconded, the following resolution, which was passed unanimously:—"That legislation should be secured to enable the responsible officers of Public Health to prohibit the sale of milk from any dairy, where infection may be reasonably believed to be traceable to that dairy."

On Friday a paper was read by Mr. Cargill Patrick, F.R.C.V.S., on the "Keeping of animals, and their influence on Public Health."

There was also a paper by Mr. P. J. Howard, M.R.C.V.S., on the subject of "Meat inspection in rural Ireland—What it is and what it should be."

In the course of Mr. Howard's paper he contended that the methods of distributing meat in rural districts in Ireland was little short of a scandal. In many cases the butcher's shop was his dwelling house and slaughterhouse combined. Where private slaughterhouses existed they were often in connection with dwelling houses, or situated where hygienic conditions were impossible. He called attention to the fact that in most of those cases, it was the very poor who suffered the most, as certain unscrupulous traders openly supplied them with meat cut from diseased carcasses. He advocated the registration and licensing of meat sellers.

A considerable discussion arose, in which Mr. Hedley, Chief Veterinary Surgeon to the Department of Agriculture, Messrs. Watson, Begg, Mason, Holland, Winter, and Cooney took part. Mr. Cooney contending that until foreign meat and Chinese pork were submitted to close inspection and branding, there could be little hope of safe-guarding the Public Health.

Mr. Cooney proposed, and Mr. Mason seconded the following resolution which was passed unanimously:—

"That the Government be called on to pay out of the Imperial Exchequer compensation for all animals purchased in the open market, and presenting a healthy appearance, which on inspection after slaughter were found to be tuberculous."

This closed the business of the Section.

Viewed from the social side, the Congress may be fairly claimed to have been an unqualified success.

On Tuesday there was a steamer left for the Pigeon House and a trip in Dublin Bay.

On Wednesday, Lord and Lady Aberdeen entertained the members of the Congress to a garden party at the Viceregal Lodge, Phoenix Park. There was a special performance in the Empire Theatre in the evening.

On Thursday Mr. Stanley Cochrane gave a Garden Party at the beautiful grounds surrounding his house at Woodbrook, Bray. In the evening the annual Congress dinner was held in the Gresham Hotel.

On Friday the Committee of the Zoological Society, gave a Garden Party at the Zoological Gardens, Phoenix Park, which was largely attended. There were also drives to Lucan and Howth.

On Saturday Sir Christopher Nixon gave a Garden Party at Roebuck Grove, Miltown. The Pembroke Urban Council also gave a Garden Party at Pembroke Park.

There were a number of other entertainments given, which were more or less of a semi-private character. The weather was brilliantly fine, and left nothing to be desired in that respect.

It has been my privilege to attend the Congress of the Royal Institute of Public Health on three different occasions. It has, however, never been my privilege to grow very enthusiastic about the completeness of their arrangements. Those who are responsible for the organisation of those Congresses may be likened to that famous French family of whom it was said that they were never able to forget anything or to learn anything. The sections were too numerous and over-lapped badly with the result that some of them collapsed altogether, and the complaints of the delegates were loud and long drawn out.

The Section of Comparative Pathology and Veterinary Hygiene, under the Presidency of Professor Mettam, went without a hitch. The delegates were not numerous, but they were most loyal in their attendance, and the discussions, although carried on under considerable difficulties, were well sustained.

It is I think a great mistake that copies of the papers presented for discussion are not in the hands of the delegates at least on the morning of the opening of those Congresses. It is not given to every man, however wide his knowledge, to be ready in debate or to be able to collect his ideas or marshal his facts in proper order at a moment's notice. The result is obviously unfair to the man, who prepares a paper at the expenditure of much time and labour, and manifestly unfair to the delegate, who is called on to speak without some preparation. There were a number of delegates from other sections attended and took part in the discussions.

With the exception of Mr. McKenny and Mr. Heeney, all the Dublin practitioners were too busy to attend. Mr. Healy, of Cork; Mr. Winter, of Limerick; Mr. Howard, of Ennis; and Mr. Holland, of Athy, appear to have the capacity for annihilating space, when space comes between them and the performance of whatever services they can, by their presence or otherwise, render the profession. In spite of some of the disadvantages that inevitably, perhaps, surround the members of the profession in attending those Congresses, it is good, beyond all question, for the profession to be represented at them.

The meeting of the Congress claimed a large amount of attention from the public and the press of Dublin. Full reports of the meetings of the different sections appeared every day, and foremost amongst those came the Section of Comparative Pathology and Veterinary Hygiene. Apart from any consideration of public expediency, it is evident the profession has made a distinct advance in identifying itself with those Congresses. It has established its claim to be considered an important factor in matters relating to Public Health, and a force to be reckoned with in any legislative measures that may in the future be projected with a view to that end.

J. J. KELLY,

CONGRESS OF THE ROYAL SANITARY INSTITUTE.

Mr. President and Gentlemen, In accordance with the Resolution passed by the Society, I had the honour of attending as your delegate the 26th Congress of the Royal Sanitary Institute at Belfast, last July.

The customary introductory proceedings of the first day were enlivened by the presence of His Excellency, the Lord Lieutenant and the Countess of Aberdeen. The evening Meeting in the City Hall, when the President, Lord Dunleath, was installed and delivered his address, being a particularly brilliant function.

The sectional Meetings and Conferences began on the Tuesday. At the Conference of the Medical Officers of Health and Sanitary Inspectors papers relating to meat and milk are frequently discussed and are therefore of interest to the Veterinary Surgeon. This year the Medical men were largely interested in the Insurance Bill, but I shall have something to say later about the Sanitary Inspectors.

At the Conference of Port Sanitary Authorities (which unfortunately was held on the same day as that of the Veterinary Inspectors) an instructive paper on the importation of unsound food was read by Dr. Hanna. Among other interesting details as to the quantities of frozen meat imported, he informs us that during last year, 1910, there were 33,365 carcasses of Chinese pork imported into Liverpool. He also considers that the uniformity of inspection and branding of meat should be considered as an International question. The Conference of Veterinary Inspectors was held on Friday. There were a good many present, but as no attendance book had to be signed and most were strangers to me, it was difficult to estimate how many of those present were members of our profession. It was a poor attendance compared with the Brighton Meeting.

A number of Medical Men and Town Councillors took part in the discussions. The titles of the papers read were as follows:—

Meat Branding and Uniformity of Inspection, by Mr. W. G. Barnes, M.R.C.V.S.

Meat Inspection in the County Borough of Belfast, by Councillor O'Neill, M.D., etc.

The New Belfast Public Abattoir, by Councillor H. O'Neill, M.D.

The Modern Abattoir and its Methods, by T. Sherwood New, M.R.C.S., D.P., J.P.

It will be observed that only one of the above papers is written by a Veterinary Surgeon, I think it is regrettable that in a Section devoted to Veterinary subjects so few of our Members should have contributed papers. Of course it may be observed that two of the papers read were of local as well as general interest and could not perhaps be omitted from the programme, but all the same I think more literature by Members of our profession would have been appropriate and welcome.

Mr. J. A. Jordan, M.R.C.V.S. City Veterinarian, Belfast, was the President of the Conference.

He gave an able and interesting address and dealt chiefly with the subject of branding or marking meat after it had been examined by a qualified inspector. He pointed out that at present the consumer had no guarantee that the meat he was purchasing had been examined and found free from disease. If, however, the system of branding were generally adopted, he would know whether he was getting imported frozen or chilled meat or home killed meat. He would also know that it had been inspected and found to be sound. The advantages of branding would not be confined to the consumer, they would also extend to the honest trader. He thought it would help to bring about a general adoption of the system if hospitals and other bodies that were large consumers of meat were to insert a clause in their tenders, that they would not accept any meat unless it had been slaughtered, inspected and branded at a public abattoir.

He regretted that owing to opposition they had not been able in Belfast to make branding compulsory. They had introduced the system of marking meat with a rubber stamp, but it was not used until after they had obtained the consent of the owner. In practice, however, it had been found that the use of the rubber stamp was not always quite satisfactory, as the ink would sometimes run and discolour a large surface of the meat. Several kinds of ink had been tried, but he had eventually overcome all difficulties by the invention of a branding iron which was heated by electricity and made a clean indelible mark, which could not be objected to.

Mr. Jordan subsequently gave a demonstration with the iron, marking some organs and pieces of meat in a most satisfactory manner, and there can be really no objection to this method of marking meat. Mr. Jordan is to be congratulated upon his invention, but it has since occurred to me that a more portable branding iron could be made than the electrically heated one, one heated on the same principle as our thermo-cautery. I think the wires must limit to some extent the area in which the electric iron can be used, besides, the current might not always be available. I can recall seeing such a cautery being exhibited at one of the meetings of this Society many years ago by Mr. Beach, M.R.C.V.S., Bridgnorth. It was very simple and very portable. I leave the settlement of this subject to those who are practically interested in it.

Owing to the unavoidable absence of Mr. Barnes M.R.C.V.S., his paper on "Meat Branding and Uniformity of Inspection," was read by Dr. Collingridge, of London.

In his paper he refers to the attention which this subject is at present receiving at home and abroad. The French Government has called an International Conference to investigate the matter, and it is hoped as the result of its deliberations definite arrangements may result in a recognised International standard of inspection, as we are large importers of meat and cattle, this subject affects us very much.

Briefly put, he considers a pure meat supply can only be secured by the adoption of a universal compulsory abattoir system, the scientific inspection ante and post-mortem of all animals intended for the food of man, and the branding or marking of all meat. The ante-mortem examination is in some instances more important than the post-mortem. He refers to the different Public Health Acts in the United Kingdom, and points out that the Act in force in Scotland is the only one which gives the veterinary surgeon a legal standing, and is besides the fairest to the butcher. He also gives some useful and interesting information as to the methods of inspection and branding as carried out in our Colonies, on the Continent, and the United States of America. Incidentally he refers to the high degree of cleanliness and sanitation which is now demanded in the latter country, since the Packing House scandal of a few years ago. I think it's very probable we shall get no improvement in our Public Health Acts until the public are thoroughly roused by an exposure of the many tricks and dodges of the screw butcher in the private slaughter houses.

The next paper read was also on Meat Inspection, as carried out in the County Borough of Belfast. The author, Dr. O'Neill, described the method adopted in the City to secure a pure meat supply to the inhabitants.

The staff there had consisted of one veterinary inspector and one assistant, four lay inspectors, and one probationer. They had a public abattoir where 25,364 animals were slaughtered last year, and of these over 8 per cent. were found affected with tuberculosis. They had also a unique establishment in the shape of a meat inspection depot where all carcasses slaughtered outside the city boundaries had to be brought for inspection before being exposed for sale. I do not know of any

other city having such a dépôt. They stamp the meat after inspection if the owner consents, as they fail to get powers to make it compulsory.

The value of the dépôt may be judged by the large numbers of carcasses cut and organs examined yearly. Dr. O'Neill considers that the successful method of meat inspection adopted in the City of Belfast is due in great measure to the experienced, well trained, and tactful inspectors employed under the immediate supervision of Mr. Jordan, M.R.C.V.S., and Dr. Baillie, Medical Superintendent Officer of Health. Dr. O'Neill laid much stress upon their being tactful. Tact prevents much opposition.

The next paper was also read by Councillor Dr. O'Neill in the new Belfast public abattoir. As may readily be guessed Dr. O'Neill is an enthusiast on the subject of meat inspection and all that relates to it, and has spent much time and energy in striving to obtain a supply of pure wholesome meat for the inhabitants of Belfast. When conducting us round the new but still unfinished abattoir, he told in the most interesting way some of the difficulties he had experienced in arousing the interest of his fellow councillors to the importance of the matter how a public abattoir was erected and meat inspection begun, then as this building became in time inadequate, how he travelled on the Continent to inspect the abattoirs and study the methods adopted there; having learned himself, he persuaded some of his fellow Councillors also to travel and see for themselves how our neighbours on the Continent managed the slaughter and inspection of the meat supplies in many of the large cities. He thus obtained their hearty co-operation in obtaining powers to have the present abattoirs erected; compared with those on the Continent, it is small, but it is well arranged and has all the best necessary appliances and is worthy of such an important city as Belfast.

I could not help reflecting what a good thing it would be if more of the Councillors in our large towns and cities were to take a similar personal interest in the welfare of the inhabitants so far as regards the meat supply; unfortunately it is the poor, who really require good nourishment, who suffer the most, but this by the way.

Dr. O'Neill's paper gives the measurements of the site, the position of the various buildings and passages, and details of the internal fittings of each. I observed that in the administrative block of buildings intended for the accommodation of the staff, there is to be a laboratory for the use of the veterinary surgeon.

We cordially endorse the hope expressed by the author that when the new abattoir is complete and in use, it will be one of the first and most complete abattoirs in Great Britain.

The next paper on "The Modern Abattoir and its Methods" for want of time was not read, but the author, Dr. Sherwood New, made a few remarks upon it and also upon a number of the instruments commonly used for slaughtering animals which he had brought; the use of the free bullet, as in the Greener killer, was condemned as dangerous, and the Behr pistol, which expels a plunger that penetrates the brain but cannot leave the pistol, was recommended as the safest and most humane. I should mention that Dr. New's paper is a most interesting one. In it he states concisely the requirements of a modern abattoir, drawing his information on the subject from Continental sources.

The discussion which followed was animated, some of the Councillors who took part were apparently anxious to fight the battles of the Council Chamber over again. In many respects this may be considered a satisfactory meeting. Both in the papers and in the discussions the position which the veterinary surgeon should occupy in this department of public health work was recognised and acknowledged. The ideal system, it was said, of

meat inspection is where the Medical Officer of Health and the veterinary surgeon are combined. I think the profession should not rest until that position is legally established.

At recent Congresses which I have had the privilege of attending, in many of the papers on subjects relating to some of the various aspects of the milk questions, I have noted appreciative references to the importance of the duties of the veterinary surgeon and the position he should occupy in public health. But in one instance at least this was not the case at Belfast. I refer to a paper entitled "The Modern Cowshed," by Mr. J. A. Sutton, Inspector of the milk supplies for Nottingham, and read at the conference of sanitary inspectors. The paper in some respects is a good one, but the author entertains peculiar views regarding the duties of administrative bodies and veterinary surgeons. Although I contradicted some of his statements at the meeting, I will take this opportunity of making some further criticisms on it. I will not trouble you with his opinion of administrative bodies further than to say he considers the inspector should be independent of the administrative body of the district where he works. He does not say, however, to what authority he should be responsible. In the early part of his paper he expresses his opinion as to the method of obtaining a pure milk supply: he says, "The better housing of dairy cows is without doubt the first thing needful for securing the purity of the milk supply, which is sent for consumption into our large cities." Now this appears to me a most misleading statement, it looks like putting the cart before the horse. I imagine most unbiased people who gave the matter a moment's consideration would conclude that the first thing needful, in fact the indispensable thing for securing a pure milk supply, is a healthy, well-fed cow. Besides it should be borne in mind that in certain places and at certain times of the year, the cows are never housed, and when this is the case the milk is by many considered the most wholesome. The main factor, indeed the only fountain and origin of a pure and wholesome milk supply is undoubtedly a healthy, well-fed cow, yet how often is this fact overlooked or forgotten in discussions about milk.

Further on in his paper he says, "The health of the cow to a great extent (in fact more than is generally recognised) depends on its environment, and particularly on the hygiene of the building in which for a greater part of the year it is housed; therefore to secure a pure milk supply we must have healthy cows and to have healthy cows we must have hygienic cowsheds." Now nearly everyone will agree with this statement, but here again he gives the cowshed an importance which it does not possess and omits to mention other matters of equal, or perhaps more importance as regards a pure milk supply. Every practical man knows that healthy cattle in the most hygienic cowshed will not long remain healthy or give good pure milk unless they are properly fed and looked after, yet there is no reference to this important fact. It is essential that we should have hygienic cowsheds for dairy cows when it is necessary for them to be housed, but the buildings are only one of the means to an end when that end is a pure milk.

I must trouble you with another rather long quotation from Mr. Sutton's paper, in which he expresses his views about our profession. "Next in importance" he says, "to the mode of administration is the qualification of the Inspector himself. Many well-known veterinary surgeons consider that the control of the dairies and cowsheds should be exclusively in their hands. Why this should be so I fail to see. I will admit that a veterinary surgeon is, or should be competent to inspect a live animal, but not being a sanitarian, he has little or no knowledge of building, the laying of drains and the multifarious details which are distinctly within the province of the sanitary inspectors. The inspection of

cattle has for its object the discovery of disease from which the cow or cows may be suffering, and the prevention of the spread of such disease through the medium of milk supply. It is not a difficult matter to find out if a cow has anything the matter with the udder, and it is very simple to take samples of milk direct from the udder and from each teat if required, and to submit the same to bacteriological examination. That is the method we adopt at Nottingham. If milk is found to contain the germs of a disease, e.g., tuberculosis, our investigation would be narrowed down until the particular animal giving it would be certain of detection. There are many other common ailments which affect dairy cattle, especially their udders, but none of these present much difficulty of detection or diagnosis if the above procedure is carried out. I have no desire to underrate the value of veterinary advisers. If the profession can prevail on municipal and other bodies to appoint another specialist to their health departments all well and good, but in my opinion the sanitary inspector is better fitted by his experience for the inspection of dairies and cowsheds than is a veterinary surgeon."

Such is the veterinary surgeon as seen through Mr. Sutton's spectacles.—I will leave you to say what you think of the picture. Your delegate and Mr. Dixon, M.R.C.V.S., Leeds, felt it necessary to at once contradict some of his assertions in view of the publicity which was given to the paper by the press. Mr. Dixon pointed out the waste of time involved by his method of diagnosing tuberculosis by simply taking samples from the udders and sending them to a bacteriologist for examination. It might take months before the diseased animal was identified. He also referred to the training in sanitation which the veterinary surgeon received at college; and thought many veterinary surgeons would criticise adversely some of the points he mentioned and illustrated by the diagrams exhibited.

Your delegate spoke, and as reported in the daily newspapers, said, "I wish to combat in the most strenuous fashion the contention in the paper that the veterinary surgeon was not a sanitarian." I also stated that part of his daily work was to point out the necessity and value of fresh air, and to insist upon cleanliness, good food, and pure water. And in this sense he was really a teacher of sanitary science. I also referred to the experience we had gained in the past, in the stamping out of contagious diseases in cattle without the modern cowshed, and that it alone would not do much to get rid of tuberculosis. Had time permitted more might have been said.

In conclusion, I would remark that I think it is hardly worth while the profession taking Mr. Sutton's views too seriously, although they show the trend of opinion in a section of public officials. We all know the value of sanitary buildings for dairy cows—as well as for other animals, and the real part they play in preventing and eradicating disease. We also know that hygienic cowsheds will not prevent errors being made in diet or management of dairy cows—common causes of illness and an impure milk supply. Neither will they prevent an epidemic of scarlet fever being spread by the milk, if any of the persons handling the milk are suffering from that complaint.

Looking back a few years on our past experience, we can remember that contagious pleuro-pneumonia in cattle was not got rid of merely by improvements in cowsheds. Neither are we getting rid of glanders in horses by improving the sanitary conditions of stables, and if we are to get rid of tuberculosis from our herds other measures far more important than the construction of the modern cowshed will have to be adopted, and these to be carried out efficiently will require the services of the trained veterinary surgeon. I repeat we (the profession) are all well acquainted with these matters, but the general public are not. Unless we take steps to

enlighten them on our past work, and also on the advantages which our improved training and scientific knowledge gives us over others in getting rid of preventable disease from our herds and securing a supply of healthy meat and milk, unless we do this we shall undoubtedly be left behind in the race for public recognition.

A. L. BUTTERS.

Prof. WOODRUFF wished to call in question the action of the Council of the Society on a particular matter. Some time ago he had felt it his duty to bring up the question of the appeal of the London County Council against the decision of the police magistrate in favour of Mr. Kirk, and the Society at a general meeting, with its usual generosity, was quite in favour of looking upon it as a professional matter and joining with Mr. Kirk in defending that decision. The general meeting had recommended that a sum of five guineas be voted to the appeal fund, and he believed that that resolution was carried unanimously. To his astonishment he found that when the matter came before the Council that decision was absolutely vetoed, and the very reverse decision was come to. Personally, he had no complaint except that it seemed to him, as a humble member of the Society, that it was an extraordinary thing that a unanimous decision at a general meeting should be reversed by the Council without any explanation being given. His object was to put some of the Councillors on their defence as to why they spoke and voted in one way at the general meeting and in another way at the Council meeting. He believed that the motion to contribute five guineas was made by Mr. Butters.

[The report was referred to, from which it appeared that the motion was proposed by Mr. Sanson, and seconded by Prof. Wooldridge].

The HON. SECRETARY said that it had been moved as a recommendation of the Society to the Council, and the Council had voted against it.

Prof. WOODRUFF wanted to know why they voted against it. When a unanimous vote was passed by the General Meeting some reason should be given why members of Council should sit there silent and vote in favour of the Resolution and vote in another way in secret conclave.

The HON. SECRETARY said that as Prof. WOODRUFF was on the Council now he could bring the matter up at the next Council Meeting and have it out amongst the Fellows.

Prof. WOODRUFF said it was a question of the rights of the General Meeting, and not a question for the Council.

The HON. SECRETARY read the Resolution, as follows: "That it be a recommendation from this Society to the Council that a subscription of five guineas be given towards the Defence Fund if necessary." He had spoken in favour of it at the Council, but others had not, and it was quashed.

Prof. WOODRUFF said he was not criticising their action, but was asking for a reason.

Prof. WOOLDRIDGE said the matter brought to light a proceeding which was very bad, namely the lack of any Report of the Council. In most Societies with which he was associated the Council presented a report to the next General Meeting. So far as he remembered that had not been the custom of their Society.

The HON. SECRETARY said it had never been done.

Prof. WOOLDRIDGE thought it ought to be done, and the present incident showed the great necessity for it. The Resolution had been carried unanimously, and it was only recommended to the Council simply because the Society as a whole had no power to make grants. It had been sent to the Council more in the nature of an instruction, as a direct recommendation that the grant should be made. Although the Council were within their strictly legal rights, he thought they had certainly

acted morally *ultra vires*. He joined Prof. Woodruff in asking that some explanation should be forthcoming, and he suggested that it should be given by the gentleman who happened to be in the Chair on that occasion. He himself had not been present at the Council Meeting, and did not remember receiving a notice of it.

Mr. MULVEY said that he had been in the Chair, but as no reports of the Meetings were published, his memory merely being that of an ordinary man he had not the slightest recollection of what did happen.

Mr. SIDNEY VILLAR did not profess to have a better memory than Mr. Mulvey, but he did recollect some of the proceedings at the Council meeting. He did not, however, propose to say what they were. If the President thought it right to give an explanation, well and good, but he did protest against the action of Professor Woodruff and the gentleman who followed him in calling upon the Council to explain its conduct. The Council had the power of spending the Society's money, indeed it was the body which was responsible for its funds, and at its meeting it undoubtedly considered this matter for a long while, and eventually thought fit not to fall in with the recommendation of the General Meeting. If the conduct of the Council was not approved the proper course would be to not re-elect its members, but not to ask for explanations which might be difficult to give at a public meeting.

Prof. WOODRUFF said there had been no open meeting of the Society since the Council came to that decision, and therefore it could not be called into question before the election of Council. It could not affect the election of Council, because that was the first opportunity which presented itself for bringing the matter up. His other point was that it was a very extraordinary proceeding for men who were members both of the General Meeting and the Council to vote in opposite ways at those meetings.

Mr. PERRYMAN thought that such a statement should not be made; the vote at the Council meeting was not a unanimous one.

Prof. WOODRUFF said that it was unanimous at the General Meeting.

Mr. PERRYMAN did not think they were called upon as a Council to give the *pros* and *cons* why they arrived at their decision, although perhaps they were wrong in not reporting that they had so decided. But he repeated that it was not the unanimous vote of the Council, so that it was not fair to suggest that the councillors voted one way at the General Meeting and differently at the Council Meeting. He did not think that was the case.

Prof. WOOLDRIDGE said it was quite possible that some of the members of Council had not been present at the General Meeting.

Prof. WOODRUFF agreed that that was so, but thought that as there was a majority against the grant at the Council meeting it was probable that some of the members had been present at the General Meeting and sat silent.

Mr. BUTTERS said there were some points which came before the Council which did not come before the General Meeting. The Council had more information with regard to the resources of the Society.

The PRESIDENT thought that most of the members of the Council had now spoken and defended themselves, but he did not think any defence was needed. The point was sent to the Council to deliberate upon, as to whether it was a proper thing to make the grant, and it had decided that it was not. In his opinion that was quite sufficient. It was a unanimous vote that the Council should be asked to consider the matter, and it had done so.

Prof. WOODRUFF said he was quite satisfied. The present proceedings were public, and, thank goodness, were reported, and that achieved his object.

The PRESIDENT did not think it was fair to ask Prof. Wooldridge to read his paper on "Botriomyces" seeing that the meeting must terminate in ten minutes. He therefore suggested that it should be postponed till the next meeting. Agreed.

A NEW ÉCRASEUR.

Prof. WOOLDRIDGE said he would like to introduce an instrument which had been invented by one of their students, Mr. Woods, viz., a new écraseur. He had intended to refer to it in dealing with the subject of botriomyces, because it was particularly useful in the excision of scirrhus cord.

The advantage of Mr. Wood's écraseur was the method by which the chain was shortened. It was on the revolver principle, so that one could use it entirely with one hand instead of requiring two. It was a very simple device, and so far as he could see it was an improvement on écraseurs already on the market. Mr. Woods' was not on the market yet, but protection had been applied for. There was a very simple way of releasing the chain. There was a spring at the back which could be pushed up, and the chain could then either be tightened or slackened as required. It slid down, and then to pull it up again one released the ratchet. It worked quite easily. It was done with a series of cogs, but there was an arrangement by which when cutting soft tissues three of the cogs could be taken at each pull, while in cutting through denser, harder tissues one could reduce the pull to a single cog, thereby increasing the leverage very considerably and cutting the tissues more easily. It also made the crushing slower and thereby reduced hæmorrhage.

Mr. Woods said that the instrument shown was only a rough working model, and the present check action would be done away with. He had a better idea, whereby one could press a spring at the side and throw it out of action for pushing forward. In old écraseurs it was found that one sometimes missed when there was a tight pull on it. He thought it was Mr. Dewar's patent where there was a special arrangement for pushing the chain forward, and one sometimes missed a cog.

He had made several models of the instrument. The first was made out of an old cigar box. Then he thought that more force could be exerted by bringing the whole of the arm under it, but he found the instrument threw up. Then he had a sort of claw which pulled it towards one, but he found a weakness in it; it might give way at an awkward moment. He had now a pushing action, so that there was no possibility of its going forward; the mere fact of pulling it back wedged it tighter than it was before. The present check action was merely done for temporary purposes; the other arrangement of which he had spoken was attached to the handle, and by just pressing a knob one would be able to slide it forward or pull it up as one wished.

So far as power went, he had found it sufficiently strong to cut through any tissue on which it might be used. (Mr. Woods experimented on a fairly thick roll of leather, but unsuccessfully.) He explained that the trouble was that a very weak spring had been put in, but it would be seen that the idea was very good.

Prof. WOOLDRIDGE said that an ordinary écraseur would find the leather very difficult to cut; it was not a fair test.

Mr. Woods said he had tried it successfully when it was in proper working order. He had found it would cut through tissue as thick as could be found in practice, and of course it was easy to clean.

The PRESIDENT said if it would cut through that leather it would cut through anything.

Mr. Woods said it had done it that morning quite successfully; he had shown it to Prof. Macqueen. The

makers had put on a check spring for temporary purposes which did not seem very satisfactory.

VOTES OF THANKS.

Mr. PERRYMAN moved a vote of thanks to the two delegates, Messrs. Butters and Kelly, for the interesting reports they had presented.

Prof. WOOLDRIDGE, in seconding the motion, expressed the opinion that the Society could not possibly have sent better representatives. They had sent a very strong fighting man over to Belfast who had beard some of the lions in their dens and had shown sanitary inspectors that there were two sides to the question, and that theirs was not always the right one. Mr. Kelly's eloquence in defending Trinity College, Dublin, was, he thought, appreciated by all present—not that it wanted any defence—and the detailed report he had presented was a very excellent one.

The votes of thanks were carried by acclamation.

Mr. BUTTERS, in returning thanks, said that as a rule such meetings as that at Belfast were very pleasant: there were many social functions which helped to make the time pass very pleasantly. Of course there was work connected with the duty, which had to be attended to, such as securing copies of the papers and making a hasty perusal of them in order to see if there was anything which required supporting or contradicting.

Mr. KELLY, in thanking the members, said that when he was informed by their very estimable and extremely energetic Secretary that he was delegated to appear in Dublin to represent the Society he felt extremely gratified and honoured, one reason being that he had but lately been elected a Fellow of the Society and was therefore a comparative stranger, and the other being the fact that the Society exercised a powerful influence in the profession not only in London but in the United Kingdom.

HUGH A. MACCORMACK, Hon. Sec.

The Alleged Ringbone Case at Castle Douglas.

Sheriff-Substitute Napier gave decision on Tuesday, in Kirkcudbright Sheriff Court in the action by Thomas Black, farmer, Parton Mill, against Hugh Crawford, cattle-dealer, Castle Douglas.

[The proof of this case appeared in our issue of Dec. 16, p. 382.]

INTERLOCUTOR:

Kirkcudbright, 12th December, 1911.—The Sheriff-Substitute having heard parties procurators and considered the cause, finds in fact (1) that on 20th May last the pursuer sold to the defender a Clydesdale gelding with a warranty of being sound so far as known; (2) that this warranty was given in good faith, and was true; (3) that the defender having asserted that the horse was lame, the pursuer and defender agreed on 29th May to refer that question to Mr. Campbell, V.S., Castle Douglas; (4) that on 30th May, about mid-day, Mr. Campbell examined the horse at Marchfield Farm, and gave it as his opinion that it was not lame; (5) that the second examination of the horse made by Mr. Campbell later on the same day, was not made with the consent of the pursuer, and Mr. Campbell's decision then given that it was unsound is not binding on the pursuer. Therefore sustains the pursuer's third plea-in-law, repels the defence, decerns against the defender as craved for £14 9s. 2d. being the balance of the price of the horse, along with the expenses of sale under warrant of court. Finds the pursuer entitled to expenses, and remits his account thereof to the auditor to tax and report.

Signed LAWRENCE T. NAPIER.

Note.—On Saturday, 20th May last, the pursuer sent a three-year-old Clydesdale gelding to be exposed for

sale at a sale then held at Diamonds Laggan. At the exposure he admits that he warranted the horse "sound so far as known." Mr. Walle's explanation as to what this warranty means will be accepted. He says it means that the seller has never seen the horse lame, and that in good faith he believes it to be a sound animal. He adds that such a warranty coming from a farmer who has had the animal in his possession for some time carries more weight than coming from a dealer who might have had it in his possession only for a day or two. The pursuer had reared the horse. Accordingly the warranty carried as much weight as such a warranty possibly could.

The first question is, was it true, and given in good faith? I think it was. The pursuer gave his evidence very frankly, and I see no reason to doubt it. His ploughmen and others, who constantly saw the horse, have been examined. None of them ever saw it lame, and no one ever told the pursuer that it was lame. It had, it is true, been treated by Mr. Campbell in August, 1910. On that occasion the horse was apparently suffering from a sprained shoulder. It was lame for a short time, but completely recovered, and Mr. Campbell says distinctly that the fact that it was then lame for a short time did not prevent the pursuer in May last from warranting it in good faith as sound so far as known. Accordingly, I hold that the warranty of sound, so far as known, was true, and was given in good faith.

The horse thus warranted was bought by the defender. After the sale the defender explained to the pursuer that he was entering into possession of Marshfield farm at the term, and asked the pursuer to keep the horse till the horse till then. The pursuer agreed to do so and took the horse back from Diamonds Laggan to his farm at Parton Mill. The defender having heard that the horse was lame wrote to the pursuer on Monday, 22nd May, to inform him that if this was so he would refuse to take it. This letter the pursuer says he received on 24th May. He did not reply to it, and though he saw the defender he did not speak to him—not from any disinclination to do so, but because he had, as he explains, other business to attend to. On Saturday, 27th, however, the defender went to Parton Mill. They discussed the matter, and resumed their discussion on Monday, 29th May, at Castle Douglas. They then agreed to refer the dispute to Mr. Campbell, and abide by his decision. The pursuer, however, says that the dispute between them was simply whether the horse was "lame." The defender said that the dispute was whether the horse was "sound."

Now the defender cannot possibly contend that he has proved that the question of the soundness was referred to Mr. Campbell, because both the pursuer and Mr. Campbell say that lameness was the sole subject of the reference. Accordingly, if the defender's statement that he only agreed to the reference if the soundness of the animal was to be decided by Mr. Campbell has to be accepted, it follows that the parties not having agreed as to what was referred to Mr. Campbell. If this is so there was no reference to him at all, and the rights of parties fall to be decided as they stood immediately after the sale at Diamonds Laggan. If this view, however, has to be accepted, then the defender is necessarily out of court, and has no case, because, as I have already explained, in my opinion the warranty of sound, so far as known, given by the pursuer was given by him in good faith, and was true.

But I think the cause ought to be decided on the assumption that the question referred to Mr. Campbell was simply whether the horse was lame. This, at any rate, is the question Mr. Campbell understood he had got to decide. The defender may be correct in stating that it is very unusual for a vet. to examine a horse for lameness alone, as, of course, anyone who knows about horses can find out whether a horse is lame, and Mr. Campbell admits that he does not think that he ever

granted a certificate for lameness alone before. But in this case, as there was nothing else ever said to be wrong with this horse except lameness, there seems no reason why this question alone might not be referred to a professional man. And I hold that it was. It was, of course, a verbal reference. Mr. Campbell agreed to act and tested the horse for lameness about midday on Tuesday, 30th May. He then found that the horse was not lame.

Questions were asked as to the tests Mr. Campbell supplied. But such questions are clearly irrelevant. It is quite immaterial how Mr. Campbell made up his mind. He was the sole judge as to what tests he would apply. But when he had made up his mind and told the parties what his decision was there was an end to the matter. An arbiter acting under an ordinary reference—for instance, a reference under a deed of submission—can recall any award and alter it until the moment that it has actually left the hands of the clerk to the reference (*Macrae v. Edinburgh St. Tramway Co.*, 13 R per Lord Shand, 270-271). This means that up to the moment when the parties to a reference have been informed by the clerk what the arbiter has decided, he is free to alter his decision. But after the clerk has informed the parties what the arbiter has decided, the arbiter cannot alter his decision. Mr. Campbell, of course, had no clerk, but he had similar rights. He could alter his opinion, or withhold it, or retest the horse or do anything he liked until he informed the parties or their representatives what his decision was. After he had done so he could not change his mind. In this case Mr. Campbell informed M'Gaw, the pursuer's servant, who had brought the horse from Parton Mill to Marchfield, that it was not lame. M'Gaw accordingly left it at Marchfield, returned to Parton Mill, and so informed the pursuer, who then considered that the matter was at an end. Mr. Campbell himself, after leaving Marchfield, went straight to the defender to tell him the result of the examination. He says "I told him the horse was trotting perfectly sound." This, I hold, ended the matter. Mr. Campbell could not after this alter his opinion, and the parties were bound by his opinion.

No doubt this was a very informal reference, but there must be some point of time when it can be said that the question is decided. That moment must be the time when the parties or their representatives are informed what the decision is. If I am right in this, there is an end of the case.

Mr. Campbell's second visit on the 30th, when he found the horse was lame "of-near fore hoof-head," was made at the defender's request, and after he had decided the question referred to him by the pursuer and defender. What he then found cannot affect the rights of parties. Evidence has been led as to the cause of the lameness. Strictly speaking, such evidence had nothing to do with the question in dispute. Whether the horse was lame from ringbone, or because its hoof was injured is immaterial. The only question when Mr. Campbell examined the horse, was whether it was lame at that moment. Accordingly, if I had held that the opinion Mr. Campbell gave on his second visit—namely, that the horse was then lame—was binding on the parties, the defender would have succeeded. Even if the pursuer had proved conclusively that the cause of the lameness was due to some injury to its hoof which the horse may have received after leaving Parton Mill, such as by kicking it against the side of the loose box at Marchfield or in some other way, the defender would have been entitled to found on Mr. Campbell's decision and refuse to take it. I, however, accept Mr. Campbell's opinion, supported as it is by the high authority of Principal McCall, that the cause of the lameness was ringbone. Mr. George Nicholson does not really differ. He says, "I cannot say that I examined for ringbone." He saw a bruise above the

coronet of the near fore leg, which accounted for the temporary lameness which he saw. There were thus two causes of lameness. The latter has fortunately now disappeared. Perhaps the former will also disappear. Finally, although one may have some sympathy with the defender, still it is clear that he has got what he intended to buy, namely, a horse that was sound so far as the pursuer knew.

Dumfries and Galloway Courier and Herald.

Complimentary Dinner to Prof. Mettam.

A very successful dinner was held in the Dolphin Hotel, on Saturday evening, Dec. 9. It was given by the students and staff of the Royal Veterinary College of Ireland to their Principal, Prof. Mettam, B.Sc., M.R.C.V.S. to mark the occasion of his election to the Presidency of the Royal College of Veterinary Surgeons. The staff were represented by Prof. Craig, M.R.C.V.S., in the chair, Prof. O'Connor, M.R.C.V.S., Mr. H. W. Carbury, M.R.C.V.S. and Mr. G. Haines, Registrar. The Board of Governors were represented by Sir C. J. Nixon, Bt. M.D., President, Col. Moore, P.V.O. in Ireland, Mr. J. V. Daly, M.R.C.V.S., and Mr. F. C. Mason, M.R.C.V.S. There were also present Messrs. J. B. Dunlop, A. Watson, Municipal Veterinary Officer; J. H. Carter, London delegate for the Examinations; and his son, L. M. Magee, M. Darby, and a representative gathering of students in the College.

Apologies for non-attendance were received from Prof. Dunne, F.R.C.V.S., and Finlay Kerr, M.R.C.V.S., and others.

The toast of "The King" having been honoured the Chairman called on Mr. Walsh to propose the toast of the evening, that of Prof. Mettam.

Mr. W. P. WALSH, in the course of his remarks made reference to the all-round sportsmanship of the Principal, in not only looking with a keen eye to their interests as students, but also to their pastimes, and did all that was humanly possible to encourage both sides of their college career; and even after their leaving the College as qualified veterinary surgeons this interest was maintained, and help freely given whenever it would benefit them. When proposing the toast Mr. Walsh wished to include the name of Mrs. Mettam who also took great interest in the students' well-being and so generously helped them on many occasions, especially when they had the entertaining of the football team from the London College during their visit to Dublin.

Mr. A. O'NEILL ably supported Mr. Walsh's proposal of the toast and endorsed his words. The toast was then drunk with acclamation, the entire company present joining in singing "For he's a jolly good fellow."

Prof. METTAM, in his reply, expressed his great pleasure and pride in being invited to the dinner by his students and told of his surprise and great gratification when he was unanimously elected as President of the Royal College of Veterinary Surgeons, and that Ireland was thus, through him, honoured for the first time by having a President elected who was resident in that country and head of their College. He then gave a brief *résumé* of the history of the Royal Veterinary College of Ireland, how about eleven years ago he had first entered on his duties with a small number of students who were taught in the glass houses at that time standing on the ground now occupied by the extensive buildings of the College, and stated that the success of the College was due, in no small measure, to the Board of Governors, who rendered every aid in their power and furthered every proposition that was advanced for the good of the students of the College. He also mentioned that the position of President of the Royal College of Veterinary Surgeons was no sinecure, as his occupancy of that

position had informed him, dealing, as the Council have to do, with the interests of the whole profession, in putting down quackery, passing Bills through Parliament, etc., and seeing that the profession met with its proper recognition in every quarter. But he regretted to state that they were sadly hampered by lack of funds, and he hoped that those present, whether already qualified or approaching that goal, would aid wherever possible in increasing the income of the Royal College of Veterinary Surgeons, which at present is not expenditure, and to uphold the honour of the profession in every way.

Mr. WATSON proposed "The Royal Veterinary College of Ireland." He paid tribute to the Principal, Board of Governors, and Staff of the College, who in such a short space of time had placed the College in such a sound position that it now took second place among the Veterinary Colleges in the British Isles, and its graduates were occupying prominent positions in all parts of the Empire, and he expressed the hope that the present students would also take equally good positions.

Sir CHRISTOPHER NIXON, Bart., who, as President of the R.C.V.I., replying on behalf of the College, expressed his pleasure in being present, and complimented Prof. Mettam on his work as Principal, stating that no one had contributed more than he to veterinary science. Sir C. J. Nixon mentioned that this College also is hampered by want of funds, but he looked forward confidently to its future when it would be on a good financial basis, backed by the Department of Agriculture, which he knew had its interests at heart and would do all they could to further its interests in this line.

Mr. J. J. G. KEPPEL proposed "The Army Veterinary Service," and coupled with it the name of Col. Moore, who, he said, had done so much for the students, particularly those in their final year, in giving them the advantage of inspecting the sick lines of the Remount Depot and Cavalry, also in having with expenditure of great trouble and time started in the College a contingent of the Officers' Training Corps, which had met with great success.

Colonel MOORE, in his reply, stated his pleasure in being invited to be present at the dinner, and that he would always take the greatest interest in the College. He would recommend students when qualified, if not entering the Army Veterinary Corps, to join the Special Reserve, as this would not interfere with their private practice, and in war time the number of qualified veterinary surgeons required would be about three times as great as that required in times of peace. The necessity of having trained officers ready to go on active service was very apparent, and by joining the Special Reserve the veterinary surgeon would be benefitting himself, and in times of urgency be of great service to his country. Col. Moore then gave a short account of the raising of the R.V.C.I. contingent of the Officers Training Corps, mentioning that it was the quickest measure to go through the War Office. He congratulated the College on being the first to start a contingent in this branch of the Service.

Mr. ESMONDE W. LITTLE proposed the toast of "The Royal College of Veterinary Surgeons," which was suitably replied to by Prof. Mettam as its President, and Mr. Carter, who said how pleased he was to be in Dublin on the occasion, and to be present at the dinner.

Mr. F. C. MASON proposed the toast of "The Chairman." Prof. Craig, in a short speech, expressed the hope that all the Members would stand together and fight for the interests of the profession in general and the Royal Veterinary College of Ireland in particular. The toast was received with acclamation and all joined in singing "For he's a jolly good fellow," after which the

assembled company united in singing "Auld Lang Syne," and the proceedings terminated.

Mr. E. W. Little, who with the aid of a small Committee arranged the entertainment, is to be complimented on its success.

REVIEW.

THE STANDARD CYCLOPEDIA OF MODERN AGRICULTURE AND RURAL ECONOMY. Edited by Prof. Sir ROBERT PATRICK WRIGHT, F.H.A.S., F.R.S.E. Volume XII. Tri Z. With Appendix. (The Gresham Publishing Co., 31 & 35, Southampton Street, Strand, London.)

The final issue of a cyclopedia is often the least important instalment of the series. The initial letters of some important agricultural subjects render the volume under notice an exception to this general rule, for it contains as much of interest and solid value as any of its predecessors. Several of the major articles are of prime moment to agriculturists. Perhaps the most important are those upon the Turnip, Wheat, Weeds, Wool (including the wool industry, wool statistics, and a long section upon the wool industry of Australasia), Weights and Measures, Water (including sections upon watering, the water requirements of animals and plants, water rights, and water supply), and Tuberculosis, the long article upon this subject is from the pen of an authority—Prof. Bang, of Copenhagen. Other subjects of more than minor importance include Ventilation, Woodlands and their management, the Wintering of cattle and sheep, and Winter manuring; while two articles of special interest survey the agriculture of Wales and the United States respectively. One short biographical notice, also, will interest members of our profession—that of the celebrated veterinarian Youatt. Of the breeds of animals dealt with, the most important are those special to Wales—black cattle, cobs and ponies, mountain sheep, pigs, and terriers—the Wensleydale sheep, the large White pig of Ulster, the Yorkshire coach-horse, the Wyandotte fowl, and the Trotting horse. Finally, the work concludes with a short appendix upon subjects which have arisen or developed since its commencement. These chiefly consist of recent legal enactments, such as the Agricultural Holdings Act (Scotland), and the latest additions to the legislation concerning Animal Contagious Disease; while there is also an interesting article tracing the continued development of the Sugar-beet movement.

All that we need say, in concluding this review of the final volume of the cyclopedia, is that the completed series amply sustains the opinion we formed when reviewing the first two volumes in 1908. This work is likely to be the standard popular cyclopedia upon agriculture for years to come. Hardly any agriculturist can afford to do without it, and, while it naturally will not enlighten a veterinary surgeon regarding subjects strictly veterinary, yet every member of our profession, especially if practising in the country, will find that it contains much matter not only interesting, but also of more or less direct bearing upon his work.

Board of Agriculture and Fisheries, Dec. 26, 1911.

Action by a V.S.

At Paignton County Court, Monday, Nov. 20, Mr. Fred P. Bennett, veterinary surgeon, sued Mr. Albert Marshall, also a veterinary surgeon, for a breach of agreement, and an injunction to restrain defendant from further committing a breach, the amount of the damage being placed in the particulars at £50.

Mr. Ernest Hutchings, of Torquay, was for the plaintiff, and stated that in 1906 Mr. Bennett purchased the practice from the defendant, an agreement being drawn up between the parties, under which the defendant agreed that for a period of twenty years he would not in any manner carry on the practice of a veterinary surgeon within a radius of 25 miles under a penalty. Quite recently the defendant had returned to the locality and had set up a place at Paignton, but resided at Dartmouth.

His Honour (Judge Lush Wilson, K.C.): Do you claim the penalty?

Mr. Hutchings; No; we want an injunction to stop the defendant.

Defendant said he had been practising in the neighbourhood for many years.

The Judge, after reading the agreement, said there was absolutely no answer to it. The defendant had been paid a lump sum—and a very fair sum—for the practice, and had broken his side of the contract. The injunction would be granted.

Mr. Hutchings intimated that his client would not ask for damages.

The injunction was granted with costs.

Personal.

The Joint Committee of the Glasgow Agricultural Society and the Clydesdale Horse Society have re-elected the bench of vets. which acted last year: Principal McCall, Mr. Andrew Robb, and Mr. William Logan. They will examine all horses competing for the Cawdor Cup, the Brydon Challenge Shield, and the district premiums of the Glasgow Agricultural Society.

ARMY VETERINARY SERVICE.

Extract from *London Gazette*.

Cadet Sergt. A. C. Duncan, from the Royal Agricultural College, O.T.C., to be Lieut. Dated Dec. 23.

OBITUARY.

STANLEY CARLESS, M.R.C.V.S., C.V.D., India.

Graduated, Lond: July, 1906.

A very wide circle of relatives and friends have learnt with deep regret of the death of Mr. Stanley Carless, formerly of Worcester, which occurred on Saturday. He was riding in a hurdle race at Lahore, when his horse fell, and he was thrown with such violence as to sustain injuries which proved fatal. The sad news arrived by cable when preparations for Christmas were in evidence on every hand, and general expressions of sympathy were heard as the circumstances became known to the citizens.

The deceased gentleman was the eldest son of Mr. W. S. Carless, M.R.C.V.S., of the Butts, and Eastbourne Lodge, Britannia Square. He had held a position as veterinary surgeon in the Indian Civil Service for four years, and had an excellent prospect before him. He had assisted his father in practice in this county, and was well known in the hunting field and as an all-round good sportsman before going to India. He was a first rate horseman, and this time last year won the Lahore Grand National. Mr. Carless was only 28 years of age.

CORRESPONDENCE

THE EXPERT WITNESS.

Sir,

A careful perusal of Col. Blenkinsop's excellent paper on the above subject leads one to wish that his suggestions could be adopted in medico-legal cases. Unfortunately, however, the subject matter of the paper presents things as they ought to be, not as they are. Having had considerable experience in law cases of various kinds, both in the lower and in the higher courts, my opinion is that it will take many years before the happy state of affairs depicted by Col. Blenkinsop comes to pass. When the veterinary expert for the plaintiff is found consulting with the veterinary expert for the defendant in High Court cases, then we may expect to find the opposing counsel adopting a similar plan of campaign.

It is a well known fact that without the assistance of the veterinary expert a counsel could not conduct a horse case. No doubt if the professional witnesses on each side conformed to the ideal suggested by Col. Blenkinsop, then indeed such instruction of counsel would not be so necessary. But in the majority of cases experts will be found

who will give the most dogmatic, and often extraordinary evidence, and it is with a view to upsetting such evidence that experts on the opposite side must instruct the counsel. And in such instances the expert must "take sides" and work up the case so far as the veterinary evidence is concerned. It is not correct to assert that he cannot perform this function without sacrificing his honesty, or swearing falsely. The time to consider the proper course of action is at the commencement of the case when the facts are laid before him; if he finds that he cannot conscientiously and honestly give the necessary evidence he should say so and retire from the case. Of course I am referring to questions of opinion and not to questions of fact.

There are very few horse cases in which a substantial defence is not possible, and in a large number of instances it is difficult to state which side holds the bulk of justice and truth. This is exemplified by the manner in which verdicts are set aside when cases are taken to higher courts.

The function of an expert is not confined to giving evidence; indeed, in the majority of instances his chief importance consists in instructing counsel so as to enable the latter to cross-examine the experts on the other side and to test the veracity of their evidence. Is there anything derogatory in this? I fail to see it. If we err in this respect we do so in good company. Look through the professional journals and see the important law cases recorded from time to time, and it will be found that counsel have been instructed, and well instructed, by some of the leading lights of the profession.

Much has been said with reference to the evidence tendered by veterinary experts and the marked difference of opinion that exists in this direction. But peruse the evidence in ordinary law cases where actions for personal injuries are brought against railway companies, etc., or under the Employers' Liability Act, and what do we find? One expert giving diametrically opposite evidence to another. In the important cases medical men of the highest eminence are found on opposite sides, still no one comments on the extraordinary conflict of evidence.

I listened to the evidence in one case, in which a policeman was claiming damages for injuries sustained during a riot. Two surgeons swore that the man would be lame for life from an injury to his knee, while one appearing on the opposite side swore that he examined the man that morning, and there was nothing wrong with the knee! Even with the aid of radiography differences of opinion occur as to the existence, or otherwise, of a fracture, and the most extraordinary conflict of evidence is observed in some of these cases.

In an important case tried a short time ago, one of the jurymen asked the judge if an opinion could be formed by estimating the number of experts on each side. The judge informed him that, provided one had money enough, he could command such a number of experts on his side in London as would swamp the other side.

Now, if with the facilities in diagnosis possessed by medical men they differ in opinion on what would appear to be facts, how much more likely is it for veterinary surgeons to also differ. In many of the matters on which the veterinary expert is called to give evidence, it is impossible to say which opinion is the correct one. Take the question of "coarse hocks" and spavin. Who can decide, provided the horse goes sound and has good hock action, unless, indeed, the animal in dispute is destroyed and the hocks examined; then it is easy to give a correct opinion. Yet a horse case of very large dimensions may at any time crop up on what would be regarded by the public as a simple question.

Again, may not the so-called "false ring-bone" be the starting point of a true ringbone, at least in some instances? Do these "false" ringbones ever cause lameness?

Is there not ample room for difference of opinion with reference to the presence or absence of navicular disease? In many cases either time or a post-mortem examination will be necessary in order to prove whose opinion is correct. Unfortunately these factors cannot be made use of when the case is a medico-legal one.

No doubt in time veterinary surgeons will learn to be less dogmatic in their opinions on matters of this kind, and also will appreciate that certain nervous and respiratory

diseases may be intermittent in their development. But so long as the present dogmatism exists experts will be necessary in law cases, and will be of vital importance to the conduct of such cases.

It is possible that in the future the human race may arrive at so civilised a state and become so honest and conscientious that law cases will be few and far between, and disputes will be amicably settled without recourse to the Law Courts. But until that Utopian stage is reached, lawyers and experts will flourish, and the latter will be found indispensable to the former.

Does the expert desire that his client should win the case? Most certainly, if it was not a genuine case then indeed the expert would be ill-advised to have anything to do with it. But provided there is room for honest difference of opinion, the expert is fully justified in instructing counsel, and attending consultations of counsel on behalf of his client. He is well paid for his services—or at least it is his own fault if he does not demand and receive a substantial fee.

Personally, I enjoy an important horse case, provided I do not figure as the defendant in same, and that I have intelligent counsel to deal with, and an honest and liberal client. More especially does such a case give pleasure when the experts on the other side are of the Sir Oracle type, and exhibit a spirit of dogmatism which is out of all proportion to their knowledge of professional matters, as elicited by cross-examination.—Yours, etc.,

"LATITAT."

VOMITION IN THE HORSE.

Sir,

The short account recorded by Mr. Hamilton Kirk last week of manifestations of this unusual symptom in the horse, brings to my mind the first occasion I witnessed it, now many years ago. It was at our local Steeplechase Meeting where one of the horses had fallen heavily upon landing over a drop fence. Upon making a careful examination soon afterwards the only alarming symptom was occasional spasmodic contraction of the cervical muscular, accompanied by a discharge of ingesta from both nostrils. Having been taught by teachers and text-books that vomition was a diagnostic symptom of serious abdominal lesion—probably ruptured stomach, I, of course, prognosed most unfavourably, but to my surprise the animal very soon recovered. I witnessed the condition many times when in South Africa, generally as a result of heavy falls, some ending fatally and others making quick recovery. Although in charge of three shiploads of horses for the Boer war, during one of which many of the animals got terribly knocked about, I have not witnessed the symptom at sea.

THOS. A. HURAND.

Kingsdown, Sevenoaks.

HOW LONG CAN A HORSE REMAIN UNDER WATER?

Sir,

I was coming in a train about two months ago from the Argentine to Valparaiso, and the course of the line is that of the Acoucagua river. It is two miles wide when the snows are melting, but at times is merely rivulets. The bed is composed of large stones, on the underside of which grows a species of riverweed. The native horses are very fond of this, and the natives turn them out to feed on it. The depth of the water on this occasion was about 50 centimetres, and the horses were feeding with their heads completely immersed. We watched them for some time and decided to time them how long they could keep their heads under water. The best times are as follows:

4 minutes	35 seconds
4 "	2 "
3 "	32 "

All these times were taken with a Benson chronometer. I am assured it is no uncommon thing for a mare to foal in the river, but until I see one I shall refrain from writing on the subject, nevertheless it is a fact the horses of the Acoucagua valley live a semi-aquatic life.

Prophylaxis and Treatment of Influenza and all Febrile Diseases of Horses.

INFLUENZA ANTITOXIN VETERINARY (P., D. & Co.), obtained from the blood of horses which have been immunised against influenza, is a remarkably efficient agent both for the prophylaxis and treatment of febrile diseases in horses, particularly influenza (pink-eye, catarrhal fever or shipping fever) with its complications of cough, laryngitis, bronchitis, strangles, pneumonia and purpura hæmorrhagica.

Mr. G. J. Bissell, who maintains a racing stable in Kentucky, and who has had considerable experience in shipping horses, writes as follows:—

"It is now over two years since I started to use your Influenza Antitoxin as a preventive. Since then I have never had a case of influenza. I have shipped young horses from Canada to Cuba and back. Formerly I carried \$16,000 to \$20,000 insurance on my stable of race horses; now I carry very little, although I have in training from twenty to thirty horses. If it had not been for your Influenza Antitoxin I would have certainly given up a racing stable of horses."

J. E. King, Assistant State Veterinarian, St. Louis,

after four years' experience with Influenza Antitoxin, states that it will abort strangles and cause the tumours to gather and discharge in from 24 to 36 hours, and in pneumonia it enables the veterinarian to save 90 per cent. of those grave cases which invariably die under medicinal treatment alone.

G. W. Dunphy, Consulting Veterinarian of the Michigan State Live Stock Sanitary Commission, states:

"Its power to arrest the action of the influenza toxin seems almost phenomenal."

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass only.** The glass barrel is ground inside perfectly true to cylindric form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The Needles are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Price with 2 Steel Needles in Metal Case—20c.c. 21/- 10c.c. 17/6. 5c.c. 15/- 2c.c. 10/- 1c.c. 9/-

PRACTICES FOR DISPOSAL

PURCHASERS ARE REQUESTED to call, or write stating their requirements, as we have numerous Practices on our Register which have not been advertised. *No charge* is made to purchasers.

To Vendors.

WE make no charge unless a Sale is effected. If you have a genuine Practice you wish to sell quickly and without publicity we shall be pleased to place particulars on our Register.

PROSPECTUS, containing "*Hints to Vendors*" and "*Hints to Purchasers*," post free on application.

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

THROUGH ill-health, a mixed practice on the South Coast will be sold for £600. Returns average nearly £700. Working expenses light. Rent £60. Good scope for increase. Every opportunity for investigation.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

Professional Advertisements.

These will be received up to Thursday morning.
Five lines or under 2/6 (exclusive of heading): for two insertions 4/-; for three 5/-; after three 1/- each.
Each line above five—first insertion 6d; after first 3d.
Average—seven words in a line.

These Advertisements will not be inserted unless prepaid, and if replies are to be received at this office an extra sixpence must be included.

As Assistant or Locum

WANTED post as assistant or locum, probably with view to partnership, in good-class practice. Good experience and excellent references. Address, 1011 V.R., 20 Fulham Road, London, S.W.

As Assistant or Locum

THOROUGHLY practical man desires situation as above. Sound experience in town and country. Excellent references. Address, 1012 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

RELIABLE man for mixed practice; must have had experience with cattle practice. State age, height, and give references. Address, 1013 V.R., 20 Fulham Road, London, S.W.

As Locum or Assistant

MR.C.V.S. requires post as above. Excellent references, thoroughly practical, and experienced in both town and country practice: good operator, especially canine. Moderate salary. Address, 1014 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

FOR mixed country practice, hunting district. State age and experience. Must be strictly sober, and no one need apply unless requiring a permanent situation. Address, 1015 V.R., 20 Fulham Road, London, S.W.

Wanted

QUALIFIED locum for small mixed practice at the end of January, for about a week. Address, stating references and salary required, to 1016 V.R., 20 Fulham Road, London, S.W.

For Disposal

GENUINE country practice: receipts exceed £700. Premium £500. Valuation optional. Address, 1017 V.R., 20 Fulham Road, London, S.W.

As Assistant or Locum

CLASS D student, twice rejected, requires situation as assistant or locum, from now to May, in a good country practice. Can ride and drive, and had plenty of previous experience. Address, 1018 V.R., 20 Fulham Road, London, S.W.

Mallein and Tuberculin

MEMBERS of the Profession may obtain Mallein and Tuberculin on application to the Principal, Royal Veterinary College, Camden Town N.W., on the following terms: In bottles, 6d. per dose; minimum quantity supplied, two doses. In hermetically sealed tubes, containing one dose each (specially suitable for use abroad), 1s. per dose.

Assistantship Wanted

BY unqualified man, experienced in town and country practice, good all-round operator. Castrate standing and not afraid of work. Address, S.W., Ingatstone, Blenheim Road, Caversham, Reading.

Assistant Wanted

FOR a West-end London practice, a qualified assistant. State age, where last employed and salary required. Address, 1019 V.R., 20 Fulham Road, S.W.

For Disposal

GENUINE country practice, market town, Yorks. C.C. appointments. Receipts about £300, introduction. Must be sold, £50. Address, 1123 V.R., 20 Fulham Road, London, S.W.

For Disposal

GENUINE old established town and country practice in North of England. Over £600 per ann. and scope for great increase by energetic man. Excellent house and stabling. Every investigation courted. Long introduction and assistance given. Present practitioner retiring. Premium £450, part of which may remain. Address, 5129 V.R., 20 Fulham Road, London, S.W.

As Assistant or Locum

RECENTLY qualified veterinary surgeon requires situation as assistant or locum in good mixed practice. Excellent references. Ride, drive and motor cycle. T. L. Shea, Castle Coote, Roscommon.

Assistant Wanted

QUALIFIED assistant, with experience for town and country practice, in hunting district. Good canine surgeon preferred. Send references and terms required. Address, 5123 V.R., 20 Fulham Road, London, S.W.

To Veterinary Surgeons

VETERINARY Surgeon with large mixed old established practice near London, is desirous (for private reasons) of exchanging same for one of equal value. Returns average £2,200 to £2,400 (veterinary alone), in first-class neighbourhood. Particulars in strictest confidence. Address, 2512 V.R., 20 Fulham Rd., London, S.W.

For Sale

SET of Pathology Notes, London College. Typed ready for binding. Price, £1 1s. Address, 1512 V.R., 20 Fulham Road, London, S.W.

For Disposal

OLD established veterinary practice: owner retiring. Address, Campbell, Maesygelly, Rhayader, Radnorshire.

All communications respecting advertisements should be addressed to

H. & W. BROWN, 20 Fulham Road, London, S.W.

Tracheotomy Tubes

MISS JONES, successor to F. B. Jones, M.R.C.V.S., still continues to supply the Special Tracheotomy Tubes patented by her late father. Special terms to Veterinary Surgeons. Address, 86 Kimberley Road, Leicester.

The Journal of The Board of Agriculture

ISSUED on the 15th of each month. Twelve months 4/-, three months 1/-, or single copies 4d., direct from the Board of Agriculture and Fisheries, 4 Whitehall Place, London, S.W., or through any bookseller.

As Locum

EXPERIENCED M.R.C.V.S., will act as locum, town or country practice. Free Dec. 30th. Address, J. B. Taylor, M.R.C.V.S., Shawlands House, by Larkhall, Lanarkshire.

As Assistant

UNQUALIFIED assistant, son of V.S., aged 26 desires post in good mixed town and country practice, permanency if possible. Energetic, good dispenser and book-keeper, and well up in all branches: ride, drive and cycle. Excellent references: previous situation 18 months, disengaged 31st Dec. Address, 4123 V.R., 20 Fulham Road, London, S.W.

Assistant Wanted

FOR country practice, must be able to do standing operation, and well up in cattle practice. State age, references. Sign bond. Address, 3121 V.R. 20 Fulham Road, London, S.W.

THE
Art of Horse-Shoeing

BY WILLIAM HUNTING, F.R.C.V.S.

THIRD EDITION,

Enlarged, with 46 new illustrations

Reprinted. Seventh thousand.

Price 5/-

Chapters on—Form and Action of the Foot; Preparation of the Hoof; Foals and Unshod Feet; Form and Manufacture of Shoes; Fitting and application of Shoes; Roughing, Injuries from Shoeing; Bad Feet; Shoe Pads, etc.

H. & W. Brown,
20 Fulham Road, London, S.W

For Disposal

SNUG practice in fashionable resort in the West, returning £200, capable of being doubled by canine practitioner. Will sell at low figure. No opposition. Address, 4087 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885 at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

Replies to Numbered Advertisements

WHEN replies to several of these advertisements are sent to this office at one despatch, it is not necessary that they should be stamped separately: they may be enclosed in one envelope, but should be marked outside "Replies."

CHEAP BOTTLES.

A large quantity of named medical bottles (these have various chemists' names on and washed ready for use)
2oz., 3oz., 4oz., 6oz. and 8oz. at 5 6 a gross.
10oz., 12oz., and 16oz. at 7/- a gross.
Cash with order. Carriage paid on £3 orders within 70 miles, and on £5 orders any distance.
Other bottles and jars quoted for.

F. NEEDHAM,

Beaconsfield Road, Acton Lane,
Chiswick, London, W.

UNIVERSITY OF LONDON.

The Brown Animal
Sanatory Institution.

In accordance with the will of Mr. Brown
A COURSE OF FIVE LECTURES
will be delivered by the SUPERINTENDENT
(F. W. Twort, Esq., M.R.C.S., L.R.C.P.)
in the Theatre of the Royal College of
Surgeons of England, Lincoln's Inn
Fields, W.C., on Monday, 8th; Tuesday,
9th; Wednesday, 10th; Thursday, 11th;
and Friday, 12th of January at 4 o'clock.

Subject:—

**A Study of Johne's Bacillus of Cattle
and
The Lepra Bacilli of Man and Rats.**

The lectures are free to the public.

HENRY A. MIERS, Principal.

An Appeal.

Victoria Veterinary Benevolent Fund.

The President and Members of Council of the Fund venture at this season to appeal to the Members of the Veterinary Profession to become **Subscribers of at least Ten shillings and sixpence Annually** to their fund. This sum entitles membership.

The object of this Society is to afford financial assistance to necessitous and deserving Members of the Royal College of Veterinary Surgeons, and to widows and children of deceased Members of the Profession who may be in poverty. The following are some of the persons who are now receiving grants:—

- 1 Veterinary Surgeon, age 85. Only source of income, Old Age Pension.
- 2 Widow of Veterinary Surgeon who died in Rhodesia, 7 children. No income.
- 3 Widow of Veterinary Surgeon, only source of income 4s. a week from son, a motor scout, and 2s. 6d. a week from the parish.
- 4 Widow of a late eminent Scotch Professor, age 84, only source of income Old Age Pension 5s. a week.

And other cases; entailing an expenditure of £150 a year, with only an income of £113 from annual subscriptions. At the next Quarterly Meeting of the Council at least six further applications for relief will be considered, and it is earnestly hoped that sufficient additional funds will be forthcoming to alleviate distress through the winter season.

President: W. FREEMAN BARRETT, Esq., Fountain Court Temple, E.C.

Council:

Abson, J., Norfolk Street, Sheffield
 Almond, N., Kingston-on-Thames
 Banham, G., 32 Rock Road, Cambridge
 Bower, W., East Rudham, Norfolk
 Burt, W., Jr., Brighton, Sussex
 Dewar, Professor, Edinburgh
 Dollar, Jno. A. W., 56 New Bond Street, W.
 Dunstan, J., Liskeard
 Garnett, F. W., J.P., Windermere
 Gooch, F. L., Stamford Baron
 Heatley, T. G., Woodbridge
 Hobday, Professor, Kensington, W.
 MacCormack, H. A., Tufnell Park, N.
 M'Fadyean, Sir John, London, N.W.
 Macqueen, Professor, London, N.W.

Mulvey, W. J., Chelsea, S.W.
 Mulvey, W. S., Chelmsford
 Penberthy, Prof., Newnham, Gloucester
 Shave, Professor, London, N.W.
 Sheather, C., London, N.W.
 Simpson, P. J., Maidenhead
 Slocock, S. H., Hounslow
 Spicer, Arnold, Oxted
 Sumner, F., Liverpool
 Stockman, S., London, S.W.
 Trigger, R. C., J.P., Newcastle, Staffs.
 Villar, Sidney, Amersham, Bucks
 Wharam, S., Leeds
 Whitlamsmith, H. H., London, S.E.
 Woodruff, Professor, London, N.W.

Any member of this Council will answer enquiries and give information as to the work that the charity is doing.

Subscriptions should be sent to the Hon. Secretary and Treasurer,
Mr. W. SHIPLEY, F.R.C.V.S., Great Yarmouth.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1226.

JANUARY 6, 1912.

VOL. XXIV.

THE INTERNATIONAL VETERINARY CONGRESS.

Mr. Stewart Stockman, the secretary of the Organising Committee, has issued a notice calling a meeting to report progress. This Committee at present confines its attention to the collection of funds, and a heavy task they have. The Congress will not be held in London till 1914, but it was thought that many men might give a subscription annually, which would total an amount before the meeting in excess of any sum payable at one time. Some few handsome donations have already been made. A number of annual subscriptions are promised, and most of the Veterinary Societies are giving help. Although membership of the Organising Committee is not limited to subscribers of ten guineas, anyone who chooses to subscribe that sum automatically becomes a member. Gentlemen desirous of contributing, or of joining the Committee, should communicate with either the secretary, Mr. Stockman, or the treasurer, Mr. Garnett.

THE ROYAL VETERINARY COLLEGE.

Every one knows that there has been a falling off in the number of students joining veterinary schools. Probably we have now reached bottom, and pupils will gradually increase in numbers. We make this anticipation not from merely a lively optimism but because there are even now openings for veterinary surgeons in excess of efficient men to enter them.

In the meantime Veterinary Schools suffer financially, and the oldest of the schools has been hard hit. On another page we reprint from *The Times* a long article pleading for Government aid. The arguments of the writer seem to us weighty and clear—in fact unanswerable. What the veterinary profession has returned to the public for the voluntary contributions and the State assistance which enabled veterinary science to make a beginning, more than repays any debt we incurred. There are still diseases to conquer, still researches to make, and any check upon veterinary progress would now be a drag upon preventive medicine.

We sincerely hope that *The Times* article will attract wide attention, and that the Royal Veterinary College will receive the Government help it needs and deserves. It seems curious that while "Retreats for Aged Animals," "Sanatoria for Cats," "Dumb Creatures Associations," etc., can collect what money they want, the Royal Veterinary College never receives a legacy, but is expected to provide every subscriber of two guineas with three

guineas worth of advice and material. The College has been too modest. It must follow the example of the Hospitals, and make its appeals to the public loudly and incessantly.

THE MALLEIN TEST AND ITS "VAGARIES."

By H. G. SIMPSON, F.R.C.V.S.

So much has been written on the subject of Glanders and the Mallein Test, and so ably and exhaustively has it been propounded by many eminent professional men that it would appear incongruous and superfluous to add to or detract from what appear unquestionable conclusions. I venture to think, however, that a discussion on what might be termed its "vagaries" may prove interesting to some who have been inclined to pin their faith to a hard and fast rule in diagnosis. Very few will question the obvious character of the symptoms produced in a definite reactor, and nobody is likely to make a mistake in a non-reactor, but the cases I wish to draw attention to are those in which either or both the thermal and local disturbances are of such a character as to leave a doubt whether one might safely give an opinion on the result of two testings, as they often require to at present.

I have been fortunate, inasmuch as I have been enabled to keep under close observation several horses that might be described as the "tail end" of an outbreak of glanders—horses which were included in an official County Council test and which (under present regulations) after the second test had to be pronounced free or infected upon the reading of the mallein test. These are the horses which I think any veterinary inspector will agree cause him many pangs and heart burnings.

As the position stands at present, should an inspector be in doubt as to the reading of the first test, the horse is very properly put aside for a further test, but no further official opportunity of watching a suspicious horse is *legally* afforded an inspector after his second test—at the expiration of that period he has to say definitely "passed" or "condemned" and the horse is lost sight of afterwards. Should he condemn the horse on a *suspicious* but not definite reaction and the post-mortem reveal no glanderous lesion, his Council through his act become liable for full compensation, and the test is possibly held up to ridicule as unreliable. On the other hand should he pass the animal and the horse show evidence of the disease later on, suspicion is cast on his judgment, and horse-owners will again comment severely on the supposed infallibility of the mallein

test. The majority of horseowners are in favour of the test, and even when the "official" supervision of a stud had ceased after the second test, if the inspector communicates to them his suspicions of certain horses, they will, in their own interests isolate and keep these animals under observation till a more definite opinion can be arrived at. There is, however, no power over the unscrupulous owner, who is at liberty to distribute suspicious horses broadcast and possibly create fresh centres of infection. If glanders is to be eradicated (and there is no reason why it should not be) veterinary inspectors must be granted increased powers in dealing with "suspicious" horses.

In a small way to demonstrate the necessity of a proper supervision on "suspects," I will quote three cases:

No. 1. Bay Mare (23). Tested twice by Council, and after a *suspicious but indefinite* reaction passed out of official control; was sent to an isolation depot and became "clinical" within a month.

No. 2. Roan Mare (2875). Tested officially twice, and after a *suspicious but indefinite* reaction passed out of official control; was sent to an isolation depot and became "clinical" in ten days.

No. 3. Roan Mare (2959). Tested four times under Inspector "A," and after a last suspicious reaction removed to isolation depot in Inspector "B's" district, who condemned her on his second test with an indefinite reaction; her post-mortem showed glanders.

In the above, the first two cases became "clinical," one within a month and the other within ten days of having given indefinite final reactions—and here comes in the hardship to horseowners. Two working animals valued at £40 apiece at last test would have reimbursed their owners to the extent of half their valuation, whereas the result of the final test being still indefinite and insufficient to warrant the Local Authority risking the chance of having to pay full value at the time, they become what are commonly known as "forty bobbars" shortly afterwards, the expense then falling on the owners. Apart from this there was the chance of their creating fresh centres of infection, as the Local Authority had no *legal* control over them, and it was discovered on post-mortem that Case 1 had lesions in the trachea. Case 3 is one that theoretically might have cast reflections on the inspector who in the first place lost legal control over her in her first testings. As the second test was not conclusive she passed out of the control of Inspector "A"—she was condemned by Inspector "B" (into whose district she was moved) after two subsequent testings by him, both of which were indefinite, her condemnation ultimately being decided chiefly on perusing the suspicious but indefinite character of no less than six previous testings, none of which were sufficiently characteristic to condemn upon under the present regulations.

We require legislation to have power of control over any "suspicious" animal, but it must be of such a kind that it will not irritate or disorganise working efficiency. It will require the co-operation of owners to render it efficient—this will un-

doubtedly be forthcoming if it can be demonstrated that the scheme is beneficial to both sides.

In my opinion "indefinite reactors" should be scheduled by the local authority and tested at as short intervals as is practicable by inspectors. They should as far as possible be stabled apart from other horses and worked together; should it become necessary to remove them to another district under the same ownership the veterinary inspector of that district should be advised, and he will continue the observation. Should the animal be a good worker, the owner will not desire to part with him, and he will probably remain with him till he is "cast" or dies, or possibly breaks down and becomes "clinical," thus the official observation should not be onerous. Should a firm object to have "suspicious" horses in their stud, and prefer to decide "yes" or "no" on the second test, it should be possible to have a scheme whereby in the agreement of the parties concerned the animal should be slaughtered (provided the inspector cannot say "non-reactor free"). In such a case, should the post-mortem reveal glanders, the usual half value compensation will be paid; but should there be no evidence of glanders, it is unreasonable to expect the local authority to defray the whole of the value, but half-value should be paid, and a scheme devised by which the cost of the remaining half-value could be borne partly by the owner and partly by the local authority, *e.g.*, supposing the value to be £40, and the post-mortem show no glanders, the owner should receive £30, in which case the owner and the local authority share the loss. Should a "suspect" become "clinical" while under observation he should be treated as a reactor and half-value compensation allowed. It is possible that this last eventuality would not often occur, as in the event of a scheme of sharing the value of indefinite reactors after the second test being agreed to, many owners would prefer to slaughter their suspects and so ensure a "clean" stud.

THE RELATIVE SIGNIFICANCE OF THE LOCAL AND THERMAL DISTURBANCE.

The question has been raised as to whether the thermal or the local manifestation is most to be relied on as indicating a reaction? Although it is agreed that the "typical" reaction is, of course, a combination of both, yet the opinions of many are divided, some being guided by a partiality for thermal and others for local degrees of disturbance in a questionable reaction. Speaking for myself (and, of course, admitting the "typical" reaction) I confess that I incline more to a partiality for certain characters of the local manifestation in doubtful cases. I base my inclination chiefly on the results of observation from just over 2,000 applications of the test during the last eighteen months, and from which I have drawn the cases enumerated in the attached tables. It may be said that the fact in many cases of my gauging the temperature from the 12th hour after inoculation and not the 9th is insufficient evidence to cast reflections on thermal disturbance, but this has been done chiefly owing to circumstances compelling the test to be employed

at such times as the horses could be spared, and where it was at great inconvenience, to ascertain the 9th hour temperature in a large batch of tests. In any case where the temperature has manifested any indication, it has been credited with it. In many cases no temperature disturbance was manifested till the 12th, and even the 18th hour after inoculation in cases where the 9th hour temperature was taken.

No doubt there are many circumstances affecting an animal which predisposes to irregularities in temperature, and perhaps not the least of these is that of subjecting a horse (whose ordinary daily routine is probably between the shafts the best part of the day) to a 48 hours, and perhaps longer detention to the stable, as is often the case under the mallein test. For one thing he misses his stable companions alongside him, and hearing the noise of every day work outside, he frets himself. Although he may be quiet for a portion of the time, the majority of it is spent in "pawing" and moving restlessly about his stall. These moments of excitement are when one might expect to find an irregularity in an otherwise normal temperature record. Although perhaps under ordinary circumstance this fluctuation of temperature might not be noticed at a period during which an animal is under the test, it is worthy of considerable attention when the elevation or depression of a degree in the reading weighs heavily in the balance of deciding as to a negative, positive, or suspicious reaction, especially so when it has not been possible to take a normal temperature on two successive days preceding the test.

The effect of mallein on a healthy horse's temperature being *nil*, and the admitted effect on a glandered horse being a gradual rise, these awkward "jumps and falls" which are often experienced might in a measure be attributable to conditions extraneous to those of mallein injection. There is, however, no gainsaying the fact that the same horse may exhibit the same vagaries of temperature under the mallein test when his conditions and surroundings are more congenial to him.

A glance at the following tables will show that these vagaries are present in animals which on post-mortem revealed glanderous lesions in one or other of their stages, and will also show that they were present in animals which on post-mortem showed apparently no glanderous lesions, but there were present pneumonic or other organic conditions which may, or may not have been responsible.

In any case, I have not come across the post-mortem of a horse showing these vagaries during life in which I could detect on post-mortem no departure from the normal in some organ. Of all organs, the lung was that which most frequently showed the more extensive structural alteration. My experience has been that the injection of mallein into a (to all intents and purposes) healthy horse produces no effects either locally, thermally, or constitutionally; but this same experience has led me to the belief that the injection of mallein into an *apparently* healthy horse may at times give rise to symptoms which, although they cannot be con-

strued as a "reaction," yet produce conditions which are abnormal and point to the existence in the body of some lesion other than glanders to which the injection of mallein is antagonistic. This, of course, raises the very wide question of whether mallein can be utilised for the purpose of diagnosing other diseased conditions than glanders?

THE RELATION BETWEEN LOCAL AND THERMAL REACTIONS AND THE NUMBER AND AGE OF THE LESIONS FOUND ON POST-MORTEM.

As regards the scarcity or number of the lesions present I have ascertained no relation between these and the intensity or otherwise of the reaction produced; a practically mild reaction has often revealed on post-mortem a very heavy pulmonary infection and *vice versa*. If any relation does exist, I should be more inclined to advocate that the relationship is between the age of the lesions and the temperature reaction. I am inclined to believe that chronic lesions are less liable to produce a temperature reaction than recent ones, and that recent pulmonary lesions will tend rather to produce a temperature disturbance. In cases which on post-mortem revealed mixed chronic and recent lesions, and under observation for from 4 to 12 months (G.H. 2,657, R.M. 2,436, B.H. 3,255, and B.M. 31) it was noticed that in the first two or three tests practically no temperature disturbance was noticed and suspicion was only aroused by the "locals," whereas in the later tests, possibly owing to recent lesions making their presence felt, the temperature was more or less disturbed. This assumption of relationship is, however, modified in the case of B.H. 2,696, whose lesions were entirely chronic, and who on his last test at the expiry of 12 months showed a temperature reaction, and also to a lesser extent in the case of B.M. 3045.

As is the case with tuberculin, it is possible in chronic cases, no doubt, for the lesions to be apparently proof against the action of mallein, but one would expect this resistance to be constant unless there was definite evidence on post-mortem of the existence of more recent lesions to account for suspicious reactions. The cases, however, of B.H. 2696, in which there was no sort of suspicious reaction 2 months after a suspicious one, followed by a suspicious one 3 months later, and a practically good one 6 months following; and R.M. 2360 who, following a suspicious reaction, gave, after respectively 3 months and 2 weeks, no sign of suspicion, followed 6 months later by a typical "local"; and Ch.M. 2735, who, following a suspicious reaction, gave after respectively 2 months, 3 months, and 2 weeks, no reaction whatever, followed six months later by a typical local, and in whose cases the post-mortem revealed only chronic lesions and healed scars, would appear to somewhat negative an assumption that old chronic lesions do not respond to mallein, or might suggest that the presence of healed scars pointed to the theory that successive injections of mallein tend to exert a curative effect. At the same time, it is a little difficult to account for what one might de-

scribe as a "passive period" of 2 or 6 months in a case of indefinite reactions—a condition which can hardly be ascribed to a "tolerance" of the system for mallein.

It may be argued that these old chronic cases showing no clinical symptoms are not to be dreaded, inasmuch as they are not very liable to break down and may work for years provided they do not become re-infected, and that therefore any tendency for mallein in their case to show no reaction is not of the greatest importance. I have in mind at present at least one post-mortem which I made showing very chronic lesions, most of them calcareous, and others surrounded with a semi-fibrous capsule, with the deep lung tissue surrounding these lesions showing signs of disintegration; around this area there was a crop of recent nodules, and I am bound to say that, owing principally to the position of the recent lesions, I formed the opinion that this was not a new infection, but due to a breakdown of a portion of the chronic lesions liberating B. mallei which they enveloped.

IRREGULARITIES OF THE LOCAL MANIFESTATION.

One sometimes hears the remark "a typical local reaction," but it is at times difficult to associate a specific characteristic to the swelling of a reactor, unless it be a degree of tenderness—the contour and size varying considerably, and at times assuming an almost atypical appearance. I am of opinion that the chief characters of a positive local reaction are embodied more in the degree of pain and persistence present rather than in any specific size or conformation, although the latter often play an important part in diagnosis. I have become accustomed to describe my local manifestations under certain headings, according to the various contours and characteristics they assume, and I group them as follows:—

- | | | |
|-----------------|----------------|------------|
| (1) "Bun-like") | Painful |) Deferred |
| (2) Diffuse | Non-painful | |
| (3) Generalised | Persistent |) Double |
| (4) Elongated | Non-persistent | |
| (5) Corded | | |

Whilst all the above are associated with reactors accompanied by pain and persistence, the most commonly occurring are the first three.

The "bun-like" reaction, when it appears, I should describe as the one more generally inclined to be characteristic; assuming the appearance of a piece of dough having been taken in the hand and thrown forcibly on the neck and adhering to the place it strikes. Its shape is circular, and its circumference sharply defined, the cutis is stretched tensely over it, and it has a marked and prominent appearance.

The "diffuse" swelling is one that is frequently met with and partakes more of the nature of an inflammatory slight thickening of the skin and subcutaneous tissues adjacent to the centre of inoculation; there is nothing definite about its shape or size, and it has no prominent appearance. To a casual observer there is not much to be seen, but palpation reveals a very decided feeling of "thickness" more or less diffused: I observed this local

characteristic specially well marked in two indefinite reactors, which on post-mortem proved to be glandered (B.M. 527, and B.M. 2094), the former associated with very early lesions, and the latter with chronic one.

The "generalised" form I have only noticed associated with definitely reacting animals, and its character is very pronounced, especially as regards the manifestation of pain. From a very decided local reaction at the 12th hour the lesion extends more or less definitely up the neck almost to the ears on the affected side, and down and around the neck to the shoulder, and sometimes to the tissues posterior to the shoulder. The greatest sensation of pain is evinced with general constitutional depression. The animal starts away from an observer and groans even if the hand be raised without actually touching the part. When moved he does so with difficulty, and so to speak "all of a piece." Turning round affords him the greatest inconvenience, and in this form of progression the head is poked out and the animal has the appearance of a horse affected with tetanus. There is, of course, no question of "indefinite" reaction in such a case.

DEFERRED AND DOUBLE LOCAL REACTIONS.

These two forms are perhaps the most interesting of any local manifestations; the former certainly is rather dangerously interesting. I have observed them in both definite and indefinite reactors, one of the latter of which is still alive and has given no subsequent suspicious reaction of any sort. A close observation of horses under the mallein test will reveal the fact that the local disturbance varies very considerably in the time of its first appearance in a stud of horses; this period varying in some instances as much as from half-an-hour to three days, although, of course, the extremes are rare.

In some animals the introduction of 1 c.c. of mallein produces a slight prominence almost immediately, whilst in the majority nothing is observable after the finger is passed over the seat of inoculation to disperse the dose, but in some few cases I have observed that in the course of half-an-hour to an hour a large swelling two or three inches in diameter appears, which is quite dispersed in a couple of hours. I remember distinctly in a batch of a dozen horses I tested this swelling appeared as stated above, and the horse foreman came to me in great alarm to say that five horses had *already* started to react within half-an-hour; their temperature, however, showed no disturbance, and the enlargement had disappeared an hour afterwards, the animals subsequently passing the test. I do not know if others have had a similar experience, but it would be interesting to know if this is attributable in any way to the initial irritation produced locally by mallein in some horses, or whether it is the result of a needle injury to subcutaneous tissue. I may mention that I do not disinfect my needle after each injection, and have never experienced any ill effects in the way of local abscess formation from it.

In the case of reacting animals, the shortest period in which I was advised of an appreciable

local reaction was $3\frac{1}{2}$ hours, when it was observed to be about the size of a small walnut, accompanied by pain. The latest period in a reactor in which a "deferred" local appeared was (the case of B.M. 527, Table 1) the 3rd day, and this was observed on harnessing the mare; the post-mortem 11 days later, when the test was re-applied and a reaction obtained, showing a very recent infection.

"LUNGERS."

In a London stable in the past this condition has been a "curse" to horseowners; there is not much doubt that before the operation of the Glanders Order many chronic cases of pulmonary glanders were included under this heading. Under it would also be included gangrenous pneumonia where the lesions were of the moist and evil-smelling type. In addition to this, there is frequently found at present on post-mortem of animals which have been subjected to several applications of the test and passed, a condition of the lung which presents areas of necrotic lung tissue, more or less pronounced, in a "dry" form—either as shrivelled up lung tissue, caseous or calcareous material, or an area surrounded by a fibrous capsule. The question presenting itself is, what was the initial cause operating to produce this condition? Is it due to a previous localised attack of pneumonia or is it the result of an attack of glanders which has become cured either spontaneously or by the action of mallein on the lesions?

I think it will be found that the past few years show a decrease in the percentage of lungers; due no doubt to a better system of ventilation and management obtaining in stables, but also no doubt assisted by the operation of the Glanders Order.

To those inclining to a belief in the curative effect of mallein it would be interesting to be able to determine how many of these areas might be ascribed to previous ravages of the *Bacillus mallei*. A glance at Table 2 will show that the post-mortem of these animals showed no lesion which could be called "glanders," although suspicion was aroused at the time of testing by "vagaries," but the lesions discoverable in the majority of cases were such as would usually be classed under the heading of "Lungers." It is perhaps only a coincidence that certain horses giving suspicious reactions show a "lunger" post-mortem, but it is cause for thought whether lungers may not in some cases be detected by a suspicion on the mallein test, and whether these "lunger" post-mortems are not dead glanders lesions which, either by the curative action of mallein or a natural process, have lost their virulence and are beyond response to mallein—in other words that they are cases of glanders which have become cured.

SUMMARY.

(A) No. of horses after second test *legally* passing out of control of the Local Authority, but isolated and worked on suspicion:

2 became clinical within 1 month.

19 on p.m. showed glanders (Table 1).

7 on p.m. showed no glanders but "lunger" lesions (Table 2)

28

(B) Young horses entering which passed test on entry, but subsequently reacted and were found glandered (B.M. 527, Table 1)

1

(C) Period elapsing between detection of disease and slaughter of last suspicious horse, when application of test showed no reaction or suspicious horses remaining; 1 year, 9 months.

TABLE I.
Testing of Horses which on Post-mortem proved to be *Glandered*
showing "Vagaries" of Thermal and Local Reactions

Bay Mare 2632.

Date.	At Inoculation.	12th Hour.	18th Hour.	24th Hour.	36th Hour.	Local Reaction.
Mar. 27, '09.	99.6	102.6	102.4	102	101	A fair sized local, painful, and persistent.
May 7,	100.6	103.8	100.4	100.2	100	" " "
July 5,	100.8	100	100	100	—	No local reaction,
Oct. 16,	101	101	101	100	100.2	A good local, painful, disappeared 3rd day.
April 24, '10.	99.6	100.4	101	101	101	Smaller than any above, painful and persistent.

NOTE.—For typographical convenience, the fractions in the temperature columns are given in tenths instead of fifths.

Post-mortem. Several chronic pulmonary lesions, many breaking down; several recent ones around those breaking down.

Remarks.—The temperature was not taken into account in this case, but the local reaction is a curious one. The first two tests produced good typical local reactions; the next test is negative, the subsequent ones producing a non-persistent swelling, and a later *small* persistent one. It is curious that in view of the fact that this case showed glanders lesions in practically all its stages no appreciable temperature reaction was recorded, and the local reaction was disappointing as compared with others. It, however, indicates that the severity or otherwise of the mallein reaction is no guide to the time of existence of the lesions found.

Bay Mare 2681.

Date.	At inoculation.	12th Hour.	18th Hour.	24th Hour.	36th Hour.	Local Reaction.
May 8, '09.	99	100.8	102	102	102	Slight, painful, non-persistent.
July 5,	100.4	102	101.2	101	101	Large, painful, persistent from Sunday till Friday.
„ 11,	100	102	102.4	102.4	102	Large, painful, persistent, and a second swelling on the other side of neck at last week's inoculation.

Post-mortem. Many chronic nodules; no recent ones.

Remarks. This case was judged entirely on the local reaction. The last test was performed a week after the preceding one in which there had been a good local reaction on the near side persisting from Sunday till Friday; on the Saturday the injection was made on the off side of the neck, and by Sunday night there was not only a good local reaction on the off side, but a correspondingly good one at the seat of inoculation of the previous week—both swellings were large, hard, painful, and persistent. This case is interesting not only as showing that a horse may give a local reaction to a second dose of mallein within the space of a week, but that in some cases a double swelling may be produced.

Brown Mare 3045.

Date.	At inoculation.	12th Hour.	18th Hour.	24th Hour.	36th Hr.	Local Reaction.
May 8, '09.	101	100.8	101	101	101	Large, painful, persistent.
July 11,	100	103	103.4	103	103	„ „ „

Post-mortem. Many chronic lesions; no recent ones.

Remarks. This case was judged mainly on the local reaction, although the temperature of the last test also bore on the decision. From the character of the post-mortem lesions, they appeared considerably older than 2 months, and it is curious that no temperature reaction should have been recorded in the first test. From this one might say the local reaction is more dependable than the thermal as an aid to diagnosis.

Bay Horse 2751.

Date.	At inoculation.	12th hour.	18th hour.	24th hour.	36th hour.	Local Reaction.
May 8, '09	101.2	104.4	104	103	102	Large, painful, persistent.
July 11,	100	102.4	102	102	102	„ „ „

Post-mortem. A few chronic nodules; no recent ones.

Remarks. The local reaction was the principal guide in this case. The first testing showed a thermal disturbance which is not quite consistent with a reaction, viz., a high jump, with a gradual fall during the 36 hours. The second test shows no very appreciable temperature reaction.

Black Horse 3116.

Date.	At Inoculation.	12th hour.	18th hour.	24th hour.	36th hour.	Local Reaction.
April 18, '09	101	103.4	104	102	102	Small, painful, non-persistent.
May 19,	100.8	101.6	103.4	103.2	102	Large, painful, persistent.
July 5,	100.2	104	104	102	102	„ „ „

Post-mortem. Many chronic nodules; no recent ones.

Remarks. This case would have been condemned on the first test, but the local reaction was very indefinite. The second test gave a good local and a very fair temperature elevation, he was, however, left for two months before deciding.

Bay Horse 2514.

Date.	At inoculation.	12th hour.	18th hour.	24th hour.	36th hour.	Local Reaction.
April 21, '09	101.2	103.4	104	103.4	103	Very slight, non-persistent.
May 18,	101.2	101.2	102.6	103.4	102.6	" "
July 12,	100.2	103.2	103	103	102.2	Large, painful, persistent.

Post-mortem. Many chronic nodules; no recent ones.

Remarks. In this case the local reaction played no part in two tests, the first of which showed a temperature reaction. The very decided local reaction at the last test decided the question, although the temperature was not as indicative as in the previous tests.

Bay Mare 31.

Date.	At inoculation.	12th hour.	18th hour.	24th hour.	36th hour.	Local Reaction.
July 25, '09	101	105	104	102	101.6	Large, painful, non-persistent
Oct. 16,	100	101	105	105	101	" persistent.

Post-mortem. Many recent nodules; no chronic ones.

Remarks. This case gave a very suspicious local reaction which, however, quickly dispersed, and this, in conjunction with a peculiar "falling" temperature, tended to the belief that it was not a reaction. The second test, with the exception of a sudden jump from the 12th to 18th hour in temperature, was typical. The lesions on post-mortem were very recent and the question is—if they would have been apparent on post-mortem at the time of the first test.

Bay Mare 2584.

Date.	At inoculation	12th hour.	18th hour.	24th hour.	36th hour.	Local reaction.
March 27, '09	100.4	105	102	101.8	101	Large, painful, persistent.
May 7,	100	102	102	102	102	" " "
July 11,	102	103	103.4	103	103	" " "

Post-mortem. Many chronic nodules; no recent ones.

Remarks. This case was practically judged by the local reaction which was a good one in each test, although almost entirely unsupported by temperature reaction on the first two occasions. The jump to 105 at the first test in the first 12 hours and subsequent fall to 102 six hours later is peculiar.

Bay Horse 2517.

Date	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction.
March 27, '09,	100.4	103.2	102.8	102	102	Large, painful, non-persistent
May 7,	100	102	102	102	102	" " "
July 11,	100.4	101.4	103.2	103	102	" " persistent.

Post-mortem. Many chronic nodules; no recent ones.

Remarks. The local reaction was the principle method of diagnosis in this case. In the first two tests they were unsatisfactory and unsupported by very definite thermal reaction. In the last the local was typical, and the temperature, although not very diagnostic, was better than the previous reading.

Bay Horse 3255.

Date	At inoculation.	12th hour	18th hour	24th hour	36th hour	Local Reaction.
May 8, '09	101.2	103.2	103	102	102	Large, painful, persistent.
July 11,	101.4	101	102.2	102	101.4	Very slight, non-persistent.
Sept. 25,	102.6	103.2	102	102	102	Large, painful, persistent.

Post-mortem. A mixed infection of chronic and recent nodules.

Remarks. In view of the good "locals" produced in the first and last tests, it is curious that no "local" appeared in the second test. The case was, however, decided on the local reaction.

Brown Mare 3237.

Date	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction.
March 27, '09,	102	103·4	103·8	102·8	102·6	Large, painful, non-persistent.
May 7,	103	104	104·4	103	102·4	" " "
July 5,	101·6	102·6	103·4	103·2	102	" " "
July 11,	100	102	102·6	102·6	102	" " persistent.

Post-mortem. Many old-standing nodules.

Remarks. The "local" in the last test was typical, but the temperature was more disappointing with each subsequent test after the second. The local, except in the last test, was not good enough to condemn on, it gradually disappeared within 36 hours.

Roan Mare 2436.

Date	At inoculation.	12th hour	18th hour	24th hour	36th hour	Local Reaction
July 17, '09	100	102	102	102	101	Large, painful, persistent.
Oct. 9,	100·6	102·4	103	102·4	101·6	Small, painful, non-persistent.
Oct. 23,	100·4	100·4	101	101	101	" " "
March 20, '10	101	102·2	103	103	101	Large, painful, dispersed 2nd day.
April 24,	100·6	103·8	103·8	102·8	101	Large, fairly painful, persistent.

Post-mortem. A few healed "scars"; no chronic, but a few recent sub-pleural nodules.

Remarks. Probably the presence of recent lesions was responsible for a more definite reaction in the two last tests. The local reaction in the first test was typical, but it was 9 months before it acknowledged the test again.

Chestnut Mare 2735.

Date.	At inoculation.	12th hour.	18th hour.	24th hour.	36th hour.	Local Reaction.
March 27, '09.	100	102·4	102·4	102	102	Large, painful, non-persistent.
May 8,	101·8	101·8	103	103	101	Small, non-painful, non-persistent
July 11,	100	100·4	99	100	100	Nil.
Oct. 9,	101	103	101	101	101	Nil.
Oct. 23,	99·2	100	100·4	100	100	Nil.
April 24, '10.	101·2	102	102	101·4	101·6	Large, painful, persistent.

Post-mortem. A few old-standing deeply seated nodules.

Remarks.—The temperature in this case is no guide; except for an attempt to rise at the second test with practically no local reaction, there was no indication of a thermal reaction. The case was decided solely on the local reaction of the last test. The peculiarity is that, after a suspicious local in the first, and an attempt at a thermal reaction at the second, absolutely no reaction is obtained in three subsequent inoculations, and after an interval of six months a typical "local" appears unsupported by a temperature reaction.

Roan Mare 2360.

Date.	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction.
July 11, '09.	100·2	100·4	101	101	101	Large, painful, non-persistent.
Oct. 9,	100·4	103·4	99	100	100	Nil.
" 23,	99·4	99·6	100·2	100		Nil.
Apr. 24, '10.	100·8	102·6	101·6	101·2		Large, painful, persistent.

Post-mortem. Several healed scars, a few chronic nodules; patches of gangrene both lungs.

Remarks.—This case is exactly similar to the preceding (2735).

Bay Horse 2696.

Date	At inoculation	12th hour	18th hour	24th hour	36 hour	Local Reaction
May 8, '09.	101.2	101.4	103	102.8	102	Large, painful, persistent.
July 11,	100	99.4	99.8	99		Nil.
Oct. 16,	100.6	100	103	102.4	102	Slight, painful, non-persistent.
Apl. 24, '10.	100.4	103.4	104	103.4	103	Small, long, painful, persistent.

Post-mortem. A very heavy chronic infection in large "clumps"; no recent nodules.

Remarks.—Except in the first test where it was unsupported by a thermal reaction, the local failed in characteristics. In the last test, although painful and persistent, it lacked the characteristic shape of the mallein reaction; it was long and narrow, with lymphatic cordings. Had it not been for the rise of temperature one might have been again undecided.

Grey Horse 2657.

Date	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction
March 3, '09.	99.8	102.2	102	102	101.4	Small, painful, persisted to 2nd day.
July 11,	100.4	103	102.8	100	100	" " non-persistent.
" 17,	100.4	102.6	102.8	102	102	" " " "
Oct. 16,	101	101	102	102	102	Large, painful, persistent.
April 24, '10.	101	103	104	104	103.6	" " " "

Post-mortem. A very heavy chronic infection; a few recent nodules.

Remarks.—Except in the last test (possibly due to the recent lesions) the temperature was not definitely suggestive of a reaction that might have been ascribed to the "local," but there was no disputing the last test.

Bay Mare 527.

Date	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction
Nov. 27, '09.	101	100.2	100.2	100.2		Nil.
June 18, '10.	100	100.6	100.6	100.4		Large, painful, appeared 3rd day, lasting 2½ days.
" 29,	100	103	103.2	103	101.8	Diffuse, large, painful at 39th hour.

Post-mortem. A very recent case; only two "millet seed" nodules, one of them having an hæmorrhagic "areola."

Remarks.—From the lesions and their scarcity doubtless this case became infected between November and June. It is curious that no temperature reaction is recorded on June 18th, when a very fair one is recorded 11 days later. The animal had been passed as free, by the veterinary inspector before the "deferred swelling" of 2nd test appeared, which evinced itself after work.

Bay Mare 2094.

Date	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction
March '09.	101	102	102	101		There is no record of any local reaction.
Oct. 31,	101	102	102	101	101	Slight, diffuse, painful, dispersed after 36 hours.
June 11, '10.	101	102	102	101	101	Ditto
" 29,	101	102.6	103	103	101	Slight, diffuse, very painful, persistent at 36th hour.

Post-mortem. A heavy infection of calcareous nodules.

Remarks.—At no test, except the last had the temperature responded, and the local in three of the four tests was by no means diagnostic. Even in the last it took more the character of an inflammatory diffuse thickening of the skin. It almost looks from the obvious age of the lesions as if they were beyond response. The similarity of the temperature readings for the first three testings is peculiar.

Roan Mare 2959.

Date	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction
March 28, '09	99.4	101.4	103.8	103.2	102	Slight, non-persistent.
April 19,	100	104.2	105	105	104.4	" "
May 1,	100	102	101	100	100	" "
Sept. 18,	100.4	101.6	102.6	101.8	101.8	" painful, persistent.
Oct. 16,	101	99.8	101	100	100	" non-persistent.
April 24, '10,	99.8	100	99	99	99	Fairly large, painful, persistent.

Post-mortem. Many deeply-seated chronic nodules and healed scars: only one recent nodule.

Remarks. It was the local reaction that decided this case. On the two first occasions when a temperature reaction was evinced it was unsupported by a "local." The last test, on which it was condemned, produced nothing but a fair-sized local which persisted.

Chestnut Horse 1855.

Date	At inoculation	12th hour	18th hour	24th hour	36th hour	Local Reaction
April 21, '09,	100.6	100.2	100.6	100		Large, painful, persistent.
Sept. 4,	100	102	102	101	101	Slight, painless, "
Sept. 18,	100	101	101	100		Larger " "
Oct. 16,	100.8	100.2	100.4	101		Slight " "
April 24, '10	100	100.6	100	100		Small, painful, persistent.

Post-mortem. Several large chronic nodules and healed scars; only one recent nodule.

Remarks. There was a definite temperature reaction in this case, and the locals, although persistent were small, and in all, except the first and last test, painless.

TABLE II.

Testings of Horses which on post-mortem proved to be *Non-Glandered*, showing "Vagaries" of Thermal and Local reactions.

Brown Mare 2442.

Date.	At inoculation.	12th Hour.	18th Hour.	24th Hour.	36th Hour.	Local Reaction.
March 3, '09.	101	103.8	103.8	102	101	Large painful up to 26th hour, receded by 48th hour.
Mar. 27,	No temperature recorded, was said to have had a suspicious local.					
July 11,	102	103	103	102.2	101	Large, painless local up to 36th hour, receded by
Aug. 15,	Slaughtered.					42nd hour.

Post-mortem. No glanders; lung tissue disorganised with gangrene, and suppuration "foci."

Remarks.—The elevation of temperature at the 12th and 18th hour, combined with a local reaction rising to the 26th hour, raised the suspicions on the first test, but the gradually receding local did not confirm them. In the third test the temperature again appeared suspicious, and the character of the local reaction agreed with the first except that it was quite painless and quickly dispersed. The animal was not condemned on the last test, as the local, although suspicious, was not as characteristic as the first.

Black Mare 2835.

Date.	At inoculation.	12th Hour.	18th Hour.	24th Hour.	Local Reaction.
March 27, '09.	99	99	99	99.2	Small, painful up to 24th hour, then dispersed.
July 18,	100	100.2	100	100	" " " "
" 24,	100.4	101.2	101	101	Small, painful up to 36th hour, then dispersed.
Sept. 25,	103	103	103.4	99.8	Nil.
Oct. 16,	101	101	100	99.6	Small, painful up to 24th hour, then dispersed.

Post-mortem. No glanders; gangrene of the left lung; encapsuled portions of necrotic tissue.

Remarks.—The first two tests gave small, circular painful locals which were unsupported by a temperature reaction, and although they dispersed after 24 hours they were suspicious. The third test a week after the preceding was with the object of ascertaining if an injection on the opposite side of the neck within a week would produce a double swelling (as in the case of B.M. 2681, Table 1.); it, however, only produced a small painful swelling at the seat of inoculation, which persisted from Sunday morning till Monday afternoon and then dispersed, but there was no corresponding swelling from the previous inoculation, and it was unsupported by a rise of temperature. The fourth test is no indication as the temperature was abnormal at inoculation, but curiously this inoculation was the only one which produced no suspicions at the seat of inoculation. Unlike the preceding case, there was no temperature disturbance in this animal.

Black Horse 2578.

Date.	At inoculation.	12th Hour.	18th Hour.	24th Hour.	Local Reaction.
July 5, '09.	100.2	100.2	101	101	<i>Nil.</i>
Oct. 9,	100.4	102.6	100	100	Fair sized, painless up to 24th hour, dispersed by 36th hour
Oct. 23,	101	99.2	100.4	100.2	" " " " " "

Post-mortem. No glanders, but three patches of encapsuled necrotic tissue in left lung.

Remarks.—The test in July was applied as the animal was said to have shown a suspicious local the previous March, but the result was negative. As he was a bad "doer" he was tested three months later, producing a fair sized *painless* local, which quickly dispersed after the first 24 hours. The same symptoms being produced at the test 14 days later with no rise of temperature.

Bay Mare 2654.

Date.	At inoculation.	12th hour.	18th hour.	24th hour.	Local Reaction.
April 13, '09.	100	100	100	100	<i>Nil.</i>
Sept. 11,	99.6	99	100		Long, corded, painful up to 36th hour, then dispersed.
Oct. 16,	100.4	99.6	100.4	100	Small, painful up to 24th hour, then dispersed.
Jan. 27, '10.	100	101	100	100	<i>Nil.</i>

Sold. No post-mortem held.

Remarks.—This animal was tested in September as she was a bad "doer," and it produced an elongated, painful, corded swelling persisting till the 36th hour, when it disappeared. As there was nothing suspicious recorded in January she was sold.

Bay Mare 242.

Date.	At inoculation.	12th hr.	18th hr.	24th hr.	Local Reaction.
July 11, '09.	101.8	102	101.4	101.8	Fairly large, painful up to 24th hour, then dispersed.
Sept. 21,	No rise in temperature.				<i>Nil.</i>

Post-mortem. Old standing patches of pleurisy and solidified lung tissue.

Remarks.—This was a young mare that had made a bad recovery from pneumonia, and her wind was affected. The local was pronounced and painful for 24 hours.

Roan Mare 2795.

Date.	At inoculation.	12th hour.	18th hour.	24th hour.	36th hour.	Local Reaction.
March 27, '09.	99.6	102.4	102.6	102.6	101	Large, <i>painless</i> up to 24th, and dispersed by 36th
May 11,	100.4	101.8	101.8	101.1		" " " " " hour.
July 11,	102	101.4	100.4	100.4		<i>Nil.</i>
Oct. 9,	101	101	101			<i>Nil.</i>
Oct. 23,	99.2	99.2	100			<i>Nil.</i>

Post-mortem. No glanders. Lower part of right lung old-standing pneumonia. Left lung patches necrotic lung tissue.

Remarks.—The "locals" produced in the first two tests were identical, viz., large, circular, *painless*, they persisted till the 24th hour and dispersed by the 36th hour. The temperature made a feeble attempt at a rise in the first test, but subsequent inoculations were negative.

Bay Mare 2900.

Date.	At inoculation.	12th hr.	18th hr.	24th hr.	36th hr.	Local Reaction.
March 13, '09.	100.6	102.4	102	101	101	Slight, <i>painful</i> , disappeared after 36th hour.
Oct. 30,	102	101.8	103.2	100.8	100	" " " "
Nov. 23,	101	100	100.4	100	100	<i>Nil</i> .

Post-mortem. No glanders. Spleen and intestinal glands much enlarged and caseous, simulating tuberculosis, but no bacilli found on examination. Kidneys pale and friable; lungs and other organs healthy.

Remarks.—A peculiar constitutional depression was noticed on the occasion of each inoculation, and the animal appeared "sick" for several days, although there was no elevation of temperature accompanying it. The mare, which up to the first inoculation had been in perfect health, seemed to, in the words of the horsekeeper, go "all to pieces." She gradually wasted away and was slaughtered soon after the last test, whether this was due to any action of the mallein on the lesions present I am not prepared to say.

TABLE "A."

The Relation of the Local and Thermal Reactions to the Lesions of Glanders found on Post-mortem.

Under observation.	Tested at intervals of	Resumé of Local and Thermal Reactions.	Post-mortem.
Bay Mare 2632	2 months	Good persistent local, no temperature.	Several chronic pulmonary lesions, many breaking down; several recent ones around those breaking down.
13 months	2 "	No reaction, local or thermal.	
	3 "	Small, <i>painful</i> , persistent local, no temperature.	
Chest. horse 1855	5 months	Small <i>painless</i> persistent local, no temperature.	Several large chronic pulmonary nodules, many healed scars, one recent nodule,
12 months	2 weeks		
	1 month		
	6 months	Large, <i>painful</i> , persistent local, no temperature.	
Roan Mare 2959	1 month	Small, <i>painless</i> , non-persistent local, inconclusive temperatures	Many old-standing, deep-seated nodules, many healed scars, one recent nodule.
12 months	2 weeks	Small local, good temperature.	
	1 month	Similar to first.	
	6 months	Fair sized, <i>painful</i> , persistent local, no temperature.	
G. Horse 2657	3 weeks	Small, <i>sore</i> , non-persistent local; no temperature.	A very heavy, chronic, pulmonary infection, with a few recent nodules.
11 months.	14 "	Rather larger, <i>sore</i> , non-persistent local, no temperature.	
	3 months	Large, <i>painful</i> , persistent local, no temperature.	
	6 "	Similar local, good temperature.	
B. Horse 2696	2 months	No reaction, local or thermal.	A very heavy, chronic infection, characterised principally by large "clumps"; no recent nodules.
11 months.	3 "	Slight non-persistent local, indefinite temperature.	
	6 "	Local, <i>painful</i> but small, good temperature.	
R. Mare 2436	3 months	Small, <i>painful</i> , non-persistent local, no temperature.	A few healed scars; no chronic nodules, a few recent, sub-pleural nodules.
9 months.	2 weeks	Large, <i>painful</i> , non-persistent local, indefinite temperature.	
	5 months	Large, <i>painful</i> , persistent local, indefinite temperature.	
	1 month	Large, <i>painful</i> , persistent local, indefinite temperature.	
R. Mare 2360	3 months	No reaction, local or thermal.	A few chronic nodules; several healed scars; patches of gangrene in lungs.
9 months.	2 weeks	" " "	
	6 months	Large, <i>painful</i> , persistent, local, no temperature.	

Under observation.	Tested at intervals of	Resumé of Local and Thermal Reactions.	Post-mortem.
Ch. Mare 2735	5½ weeks	Small, non-persistent local, indefinite temperature.	A few old standing, deep seated nodules.
13 months.	2 months	No reaction, local or thermal.

		Had given suspicious local, but indefinite temp. 3 months ago.	
3 months.			
B. Horse 2514	1 month	Very slight local, suspicious temperature.	Many chronic nodules; no recent ones.
3 months.	2 months	Typical local, fair temperature.	
Blk. Horse 3116	1 month	Typical local, almost definite temperature.	Many chronic nodules; no recent ones.
3 months	17 days	" "	
B. Mare 2681	2 months	Typical local, no temperature.	Many chronic nodules; no recent ones.
	1 week	<i>Painful</i> , large, persistent local, also another at seat of last week's inoculation, other side of neck: no temperature.	
2 months			
Br. Mare 3045	2 months	Good, persistent local and temperature.	Many chronic lesions; no recent ones.
2 months			
B. Horse 2751	2 months	Good persistent local with no temperature, following after 2 months a good local, and temperature characterised by a sudden rise at 12th hour, followed by gradual fall.	A few chronic nodules; no recent ones.
2 months			
B. Mare 2094	7 months	Slight, diffuse, <i>painful</i> local, dispersing after 36 hours; no temperature.	A heavy infection of calcareous nodules throughout both lungs.
	8 "		
8 months			
	18 days	Local similar to preceding, persistent at 36th hour; fair temperature reaction.	
B. Mare 527	6½ months	<i>Deferred</i> , large, painful local appeared 3rd day after work, and lasted 2½ days; fair temp.	A very recent case; only 3 "millet seed" nodules found, 2 of them having an hæmorrhagic areola.
7 months			
	11 days	Local similar to above (B.M. 2094) fair temperature.	

TABLE "B."

The Relation of Local and Thermal disturbances to Lesions other than Glanders found on Post-mortem

Under observation.	Tested at intervals of	Resumé of Local and Thermal Reactions.	Post-mortem.
Br. Mare 2442 4 months	3 weeks 14 "	Suspicious local, no thermal. Large, <i>painless</i> local up to 36th hour, receding by 42nd hour.	No glanders: lung tissues disorganised with gangrene and suppurative foci.
Blk. Mare 2835 7 months	4 months 1 week 2 months 3 weeks	Small, <i>painful</i> local, dispersing after 24th hour, no temperature. Similar, dispersal after 36th hour Negative. Similar to first.	No glanders: gangrene of left lung, encapsuled portions of necrotic lung tissue.
Blk. Horse 2578 7 months	1 week 3 months 2 weeks	Negative. Fair, <i>painless</i> local up to 24th hour, dispersing quickly, no temperature. Similar.	No glanders: three patches of encapsuled necrotic tissue in right lung.
B. Mare 2654 9 months	5 months 1 month 3 months	A long corded, <i>painful</i> local, dispersing after 36th hour, no temperature. A small <i>painful</i> local, dispersing after 24th hour, no temperature. Negative.	No post-mortem, as mare was sold.
B. Mare 242 2 months	2 months	Negative; following a fairly large <i>painful</i> local, dispersing after 24th hour, with no temperature, 2 months previously.	No glanders: old-standing patches of pleurisy and solidified lung tissue.
R. Mare 2795 7 months	2 months 2 " 3 " 2 weeks	All negative, after showing, 2 months previous to the first test, a large <i>painless</i> swelling up to the 24th hour, dispersing by the 36th, with a temperature rise to 102.6.	No glanders. Lower part of right lung solidified from old-standing pneumonia; left lung, patches of necrotic tissue.
B. Mare 2900 8 months.	6½ months 3 weeks	Small, <i>painful</i> local, dispersed after 36th hour, very slight thermal disturbance, but great constitutional depression for several days. Negative, except great constitutional depression for about week.	No glanders: the spleen of intestinal glands much enlarged and caseous, simulating tuberculosis, but no bacilli found on examination; kidneys pale and friable; lungs and other organs healthy.

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Dec. 23, 1911

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

A general meeting of the Association was held at Wynn's Hotel, Abbey Street, Dublin, on Wednesday night, November 22nd, when the President, Prof. A. E. Mettam, occupied the Chair, and the following gentlemen were present: Jas. McKenny, Chas. Allen, P. J. Howard, J. B. Dunlop, W. H. Wilkinson, W. Cargill Patrick, Prof. J. F. Craig, J. H. Norris, and A. Watson, Hon. Sec.

On the motion of Mr. Howard, seconded by Mr. McKenny, the minutes of the last meeting were confirmed.

Letters of apology for inability to attend the meeting were received from Col. Moore, Messrs. Thompson (Lurgan), Dobbyn, Reavy, O'Brien, Jordan, Chambers, Nolan, Vahey and F. A. Heney.

The SECRETARY read the report of the Council, and Mr. Allen proposed that it be received and adopted. (Agreed.)

REPORT OF COUNCIL.

A meeting of the Council was held on November 3rd. The President occupied the Chair, and there were also present: Prof. Craig, M.A., J. B. Dunlop, Prof. O'Connor, P. D. Reavy, Fred A. Heney, B. P. J. Mahony, Jas. McKenny, Matthew Hedley, and A. Watson, Hon. Secretary.

The Minutes of last Council meeting were read and signed.

Letters of apology for non-attendance were received from W. Cargill Patrick, P. J. Howard, J. H. Norris, Lieut.-Col. Steel, J. Holland, W. H. Wilkinson and W. Chambers.

The circular letter (and resolution) from the Secretary of Committee, re affiliation with N.V.A., was read, and it was decided to refer the letter and resolution to a small committee for report.

A letter was read from the Royal College of Veterinary Surgeons relative to certain advertisements appearing in the *Sligo Times* and informing the Council that no action would be taken in the matter, for the reason that the advertisements had been inserted by a person who had no authority to do so from the gentleman whose name appeared in the advertisements.

The Royal Sanitary Institute wrote informing the Council that the Annual Congress would be held at York in August 1912, and invited the Council to send a Delegate. Mr. Reavy proposed and Mr. McKenny seconded that Mr. Watson be requested to attend as delegate from the Association, which was carried.

A letter was read from the Royal Veterinary College of Ireland stating that two students had tied for the first place at the Final Examinations held this year, and asking the Council to bestow two medals instead of the customary one. It was resolved that the request be granted, but was not to form a precedent.

A letter was read from the Amalgamated Society of Farriers asking the co-operation of the Association in a proposed revival of shoeing competitions. The Council regretted their inability to take any action in the matter.

Mr. Watson stated that circumstances would compel him to refrain from seeking re-election to the position of Hon. Secretary next January.

The General Meeting was arranged to be held on 22nd November, at Wynn's Hotel, Lower Abbey Street.

NATIONAL VETERINARY ASSOCIATION.

The President said there was a question with reference to the National Veterinary Association. It was recommended by the Council that a small Sub-Committee be appointed from the Association or the Council to report to the Association on the matter referred to in the Council's report.

It was decided to appoint as a Sub-Committee the President, Professor Craig, Mr. McKenny, Mr. Howard, Mr. Patrick, and the Hon. Secretary, who were asked to present their report to the January meeting.

CONGRESS OF THE ROYAL SANITARY INSTITUTE.

At the recent Congress held at Belfast I had the honor of attending as the Delegate of this Association.

The Congress was held under most favourable circumstances. The warm sunshine and cloudless skies left little to be desired, except perhaps an occasional draught of one or other of the sparkling beverages for which the northern capital is famed.

The various local committees left nothing undone to minister to the comfort of the visitors: various entertainments in the shape of receptions, luncheons, and excursions, were liberally provided, and I need hardly say your delegate took advantage of many of them.

Now, coming to the Congress itself I must say that it was large and representative, and included a goodly number of the fair sex, whose winning smiles and picturesque costumes added much to the appearance of the whole assembly.

All the lectures were well attended, but naturally your delegate gave most attention to that presided over by the City Veterinarian of Belfast. I don't wish to flatter Mr. Jordan, because I know he is aware of his own importance!! Still, I don't think I would be doing him justice did I not state that in his address of welcome he maintained in a worthy manner the traditions of the Veterinary Profession.

The time of this section was taken up almost altogether by a discussion--and a very animated discussion too--on the subject of "Meat Branding, and the Uniformity of Meat Inspection" presented by Mr. Barnes, M.R.C.V.S., Chief Veterinary Inspector, Islington. Considerable interest was shewn in Dr. Henry O'Neill's most elaborate description of the new abattoir for Belfast.

Various designs of humane killers and instruments for branding meat were exhibited, but none of them presented any feature of novelty except, perhaps, Mr. Jordan's 'Electric Brander.'

In conclusion, I should just like to state that the whole trend of the various speeches pointed to the Veterinary Surgeon as the man who should in future take a full share in administering the Public Health of this kingdom.

Lurgan.

J. A. THOMPSON.

The President said that a report from the delegate to the Royal Institute of Public Health had not yet come to hand.

TUBERCULOSIS.

A letter and resolutions from the Association of Veterinary Officers of Health re Tuberculosis was read by the President, who said it required a good deal of consideration. There was one thing to be considered, and that was that a Milk Bill was to be introduced into Parliament by Mr. Burns, and they would like to see how far it went. He believed that the Board of Agriculture had admitted the principle of compensation in tuberculosis, but if they were going to extend compensation the same as it was in some other infectious diseases it would be a "large order." They would want more money than for insurance.

The Hon. Sec. said it would tend to strengthen the hands of the legislature if they adopted the resolutions. It was a tall order, but on the principle of "throw lots of mud and some of it is sure to stick," it might be productive of good. He did not see that there could be any objection to the Association approving of the resolutions contained in the letter. Every member of the Association would agree with the spirit, if not with the letter, of the resolutions.

The PRESIDENT did not agree with compelling owners of property to build houses for healthy animals, the occupants to keep them in cleanly condition (Laughter).

The HON. SEC. said that the owners of the cows were the occupants in the eyes of the tax-payer.

Mr. WILKINSON remarked that there would be a good many applications for State aid.

The HON. SEC. said that there was State aid already. They could erect buildings under a grant from the Board of Works.

Mr. NORRIS said that it would cost but little money, and would give veterinary surgeons work, and do a great deal for the country. The only thing they would have to do under the resolutions would be to re-organise the Public Health Acts as at present. When the last Bill of John Burns before Parliament was withdrawn, they had practically an undertaking that the Board of Agriculture were to give compensation for udder and clinical cases. He thought the resolutions were pretty near being materialised, and he thought they should support them.

Mr. McKENNY proposed that the resolutions be adopted.

Mr. WILKINSON seconded, and the motion was carried. *Resignation.* Mr. F. W. Emery, Belfast, wrote apologising for absence and tendering his resignation from the Association.

It was decided to ask Mr. Emery to reconsider his decision.

MILK SUPPLY.

A letter was read from Mr. James Doyle, Monkstown, in which he drew attention to the fact that a Committee had been formed to consider the scarcity of milk in Ireland, the dangers of contamination, infection, etc. He considered that it was an opportunity to assert the rights of the profession in the matter of inspectorships under the Dairies, Cowsheds, and Milkshops Order, etc., and hoped that the evidence of those veterinary surgeons in a position to give it would be availed of.

The PRESIDENT said it was the intention of the Committee to take all evidence possible from members of the profession engaged in this work. He did not think he was giving any information which he should not give when he said that a large number engaged in Veterinary Public Health had already been asked to submit evidence. Everyone engaged in inspection duties would be asked to give evidence if they wished to do so.

Mr. DOYLE said it might be useful to try and bring in veterinary surgeons to do work of inspection where policemen were now doing it.

The PRESIDENT said that he thought they should wait and see what recommendations the Commission made.

Mr. NORRIS asked if the Association could not get evidence to show that laymen could not do the work of inspection.

The PRESIDENT said that he was in a position to give that information. Officials from the Local Government Board, from the Board of Works, and the Department of Agriculture were supplying them with what they wanted to know as to what powers were in existence. There were to be Medical Officers of Health and Veterinary Medical Officers of Health, to give evidence, and advertisements were to be published asking all and sundry to give evidence if they chose. They were not limiting themselves, and it was competent for any member of the Commission to suggest that certain persons should be asked to give evidence.

Mr. NORRIS said that they should send a witness from that Association.

Mr. DOYLE remarked that it was a favourable opportunity to push home the position of veterinary surgeons with regard to inspection. He had seen disgraceful cases where a veterinary surgeon had not been inspecting.

The PRESIDENT said that the idea of calling Mr. Mason was to obtain a general idea of the state of dairies throughout the country. He had as wide experience in Ireland as anyone. They would get from him a comprehensive view as to cows and the milk supply generally.

The HON. SEC. said he remembered Mr. Howard writing a paper for Cork, and he thought that he would represent faithfully the views of the Association. He was sure the Commission would be delighted to have his opinions.

Mr. McKENNY said that Mr. Mason was capable of giving the evidence, but judging from what he said at those meetings with reference to the dispensaries, he would not approve of him as representing that Association.

Mr. NORRIS proposed that Mr. Howard be appointed their representative to give evidence before the Commission.

Mr. WILKINSON seconded the motion, which was passed.

New Member. Mr. J. S. M'CANN, M.R.C.V.S., of Tullamore, was balloted and declared a duly elected member of the Association.

ROARING AND WHISTLING.

[Adjourned discussion on Prof. Craig's paper.]

E.

Mr. McKENNY : At our last meeting owing to the very able manner in which the subject of "whistling and roaring" was dealt with, and the condensed form of knowledge on the subject set forth in Professor Craig's paper, I suggested that the discussion on it be continued at this meeting, and I hope that we may now be able to so illuminate the hitherto dark clouds of mystery connected with the subject that we may be enabled to disentangle the golden cords of unexplained facts connected therewith.

Some of the facts that I more particularly allude to are the normal and abnormal sounds produced in respiration, for these vary not only in different animals but in the same animal under altered circumstances, and the sounds which under some conditions are normal, under other conditions would be abnormal—for instance, the normal sounds of breathing when an animal is galloping would be abnormal if the animal was at rest. Again, the respiratory sounds emitted by a fat horse out of work when he is galloped would be abnormal if he were in good condition, fit to race or hunt. Also the natural temperament of a horse alters the sounds. A horse with an excitable temperament when galloped may make a shriller noise in breathing than a horse with a lymphatic temper, and if a horse is ridden with its head unnaturally bent so that the larynx is pressed on, it will make a noise that otherwise it would not do. Likewise a perfectly sound-winded horse after a long journey on a dusty road, if then galloped, may make a shrill noise which ceases if his mouth and nostrils are washed out with a wet sponge, or if he is allowed to drink a small quantity of water. The respiratory sounds made by some horses having large nostrils, when slowly galloped are frequently much louder than those having small nostrils, but when the former galloped fast so that the nostrils will be fully extended, the loud flapping noise ceases, and they generally are very sound-winded horses.

It is obvious that the respiratory sounds vary very much under different circumstances, those which I have set forth are normal under the conditions described, and therefore should not be considered or unsound. Added to the foregoing Professor Craig has enumerated in his paper other sounds, which although abnormal may be but temporary and are not those characteristics of true 'whistling' and 'roaring' as laid down by the Professor from an anatomical and physiological point of view, and

upheld by all who joined in the discussion— with the exception of one gentleman who boldly informed us that although he knew that the general opinion is that the shrill sound of 'whistling' is in the inspiration, he holds that in some cases it occurs exclusively in the expiration. The variations of the respiratory sounds narrated, are as difficult to describe verbally as it would be to illustrate the sounds of music without the aid of a musical instrument, and those who are musically deaf cannot discriminate between the normal and abnormal respiratory sounds than they could the different sounds of music. A flat would be to them the same as A sharp, or a bass as a tenor voice. Although under existing circumstances it would appear impossible that even a large majority of Veterinarians could agree as to the exact sounds which denote true 'whistling' and 'roaring,' yet I believe if phonographic records were secured of sound and unsound winded horses, especially those of 'whistlers' and 'roarers' authenticated by a committee appointed of Practitioners, and these could be obtained by Veterinary Surgeons and Students at a nominal charge, each member of the Profession could, to a considerable extent be initiated by illustration of the sounds that the majority of the profession held to be those indicative of true 'whistling' and 'roaring.'

Professor Craig defines 'roaring' and 'whistling' to be a chronic condition in which an abnormal laryngeal sound is produced during inspiration. That definition indicates that 'roaring' and 'whistling' are only symptoms of a disease. If the sound is produced during expiration only or in expiration to the same extent as inspiration, he holds that the condition is not 'roaring' or 'whistling.' The difference in 'roaring' and 'whistling' lies in the pitch of the sounds produced. In 'roaring' it is low, in 'whistling' high.

I agree with this definition, and hold that the key to it lies in the fact of the abnormal sounds of 'whistling' and 'roaring' being produced in the inspiration, otherwise the loud sound known as trumpeting might by some be mistaken for 'roaring' and every shrill noise be in the opinion of some that of 'whistling.'

Indeed at the present time the fact is each veterinarian is at liberty to form his own opinion as to the sounds produced by a 'whistler' or a 'roarer,' and therefore it is not to be wondered at that there are so many differences of opinion on the subject, and this deplorable condition will continue until standard sounds of 'whistling' and 'roaring' are agreed on.

As to the cause of the sounds of 'whistling' and 'roaring,' Professor Craig's opinion as given in his paper may be correct, but I ask him to explain how it is that the removal of the Arytenoid Cartilages or the free portion of same has frequently removed the abnormal sounds.

With the pathology of 'whistling' and 'roaring' so far as the laryngeal anatomical changes which take place are concerned, Professor Craig has dealt excellently, but we need much more knowledge than that pertaining to the local lesions to explain how some 'whistlers' exhibit symptoms which indicate that extensive alterations of their larynx have taken place, yet it does not prevent them from performing feats requiring much stamina: and again, other horses that 'whistle' but slightly become distressed on comparatively little exercise. Therefore, as the laryngeal changes that take place in a 'whistler' do not always necessarily incapacitate a horse from performing feats requiring great powers of endurance, it is evident that sometimes other structures also are involved.

In my opinion, in considering the pathology of 'whistling' it is not wise to confine ourselves to the mere local changes of structure that take place and produce the abnormal sounds. I have no doubt that the paralysis of the recurrent laryngeal nerve can be, and is, caused by ailments affecting the pneumogastric nerve, and there-

fore the affections, chronic and acute of the lungs and stomach should be considered. My views on this matter were more fully expressed at our last meeting.

Professor Craig has drawn our attention to the fact that long fine necks are often seen in 'roarers.' Since his paper appeared in *The Veterinary Record* I was consulted in a matter relative to the fact. A gentleman sold a horse which had a long, fine neck, and the purchaser had it examined by a Veterinary Surgeon who condemned the horse as unsound on account of its neck, stating that although the horse might then be sound in wind it would become a 'whistler' or a 'roarer.' The purchaser then galloped and otherwise examined the horse, and bought it, and stated he would never again have a horse examined as to soundness by a Veterinary Surgeon, as the opinion given showed him it was only throwing money away. I was asked by the seller if the horse had not been bought, could he have made the Veterinary Surgeon pay for his loss. Of course I said no, but I need not tell you what I thought of the opinion.

As to 'whistling' being hereditary, I certainly am, from my experience, of the opinion it is transmitted from parent to offspring. This may or may not be, technically speaking, hereditary, but the fact remains that the offsprings of certain sires and dams are nearly always 'whistlers' and 'roarers.' At the same time, in my opinion, when we are called on to examine a horse as to its soundness, whose sire or dam we know was a 'whistler' or 'roarer,' we should not condemn it as being unsound because we are strongly of opinion it will become a 'whistler' or 'roarer.'

It may appear to some of you that my remarks on the opinions given as to the long fine necks, and horses bred from whistlers (hereditary) are uncalled for in this assembly of professional men, but grant for a moment that some veterinarians when called on to examine horses relative to soundness, condemn as unsound such horses, and state that although they then are sound in wind, they will become whistlers or roarers, and other veterinarians give their opinions in accordance with the facts that they are sound. Which of these veterinarians are acting strictly in accordance with the knowledge we possess on the subject? The former may say we give our opinion on the fact that long, thin necked horses generally become whistlers; and whistling is hereditary, therefore we condemn as unsound those horses, as at the time of examination they have defects which probably will render them unsound. And this line of reasoning also applies to other defects which are generally admitted as constituting unsoundness. On the other hand it may be held that if at the time of examination a horse is sound, that fact should be stated, and as defective formation and breeding are not defect of tissue these are not matters calling for our opinion when asked to state whether the horse at the time of examination is sound or otherwise.

Proceeding, Mr. McKenny said that Prof. Craig had asked him to state cases of whistling being transmitted from parents to their offspring. He could give many cases that he knew of sires and dams that were whistlers and their offspring invariably were also whistlers, but in the case of some stallions the fact was more remarkable, as nearly all their progeny, certainly the majority of them, became whistlers although their dams were free from it, and might have bred, to other sires, horses that remained sound.

At present he knew a very good looking sire and had seen a large number of his offspring, and they were very well-made, stout horses showing lots of breeding, steeplechasers, and high-class hunters, with well-shaped necks, and the large majority of them were whistlers. One of his clients bred three horses from this stallion and the three were whistlers—a two year old, a three year old, and a four year old. He had previously bred from the

same dam three other horses got by different stallions, and they remained sound in wind.

Mr. McKenny stated he felt sure that nearly everyone that practically knew anything about breeding horses would give the same opinion as he had given as to the transmissibility of whistling, whether they called it heredity or predisposition. Certainly the majority of the offspring of some stallions became whistlers whether their necks were long and thin, or short and thick.

Mr. ALLEN said that the man who wrote a paper and read it before his Association was entitled to their best thanks whether the paper was good, bad, or indifferent. He had carefully read Prof. Craig's paper, and in theory and practice it was the very best written on the subject. He had read everything on the subject, and had studied the matter very closely himself, so could appreciate it thoroughly. On his part he begged to return Professor Craig his sincere thanks. Professor Craig had asked a few questions, but he had explained matters so fully that there was nothing left to answer.

One question is, what is the cause of the sound known as roaring? Well, anything that interferes with the action of the muscles on the larynx. The principal cause is inflammation of the mucous membrane lining the larynx. When it becomes thickened and indurated the muscles cannot act, so then become wasted, and seldom recover their tone and strength. Over exertion causing strain of the muscles and ligament, and pressure from some cause or other. The theory that roaring is due to paralysis of the left recurrent nerve causing atrophy of the muscles of the left side is, I consider, without any proof, as lots of horses that have been roarers have perfectly recovered, which they would not if it were due to paralysis. It is stated that the disease is hereditary. I do not believe it is. No horse was ever foaled a roarer. But the diathesis or predisposition to the disease is due to shape or malformation, which is hereditary. A true-made horse may become a roarer from accident, but that is not hereditary. I have known sound stallions get roarers; and stallions that were roarers and grunters get very sound horses. I agree with Prof. Craig in all he has written in his paper, and again beg to thank him.

Mr. McKENNY said some time ago, in a conversation with Mr. Allen, he was impressed by his remarks relative to some facts which he thought might be a cause of the near recurrent laryngeal nerve being paralysed more frequently than the off, and he hoped Mr. Allen would excuse him for briefly submitting to the meeting the simple, yet perhaps the most important fact of the frequency in which the head is twisted to the near side, and sometimes necessarily with a severe jerk, as for instance, we catch a foal on the near side, cavezon, and lead on the near side, and unfortunately when training, most grooms ring a great deal more to the near than to the off side, and in the case of a highly nervous or unruly animal, have occasion to pull the head with much force to the near side. We saddle, mount, and harness from the near side, and as a result of this perpetual handling from the near side, the structures of the near side of the neck are interfered with more than they are on the off side, and consequently may to some extent, be a cause of the left recurrent nerve becoming paralysed more frequently, and prior to, the right becoming affected.

Mr. Allen also mentioned to me that he noticed that in cases of navicular disease occurring in one fore foot, he invariably found it was the off fore was affected, and when it occurred in the near, the off fore was also affected. The handling referred to brought the off fore foot more forcibly to the ground than the near one, and this might account for navicular disease occurring more frequently in the off fore foot than in the near fore foot.

Mr. ALLEN—In nineteen cases out of twenty.

Mr. HOWARD said he thought it would be a very happy solution to the question, if, as Mr. McKenny said,

they could arrive at some definite conclusion as to what would be recognised by the profession universally as 'roaring' and 'whistling' and the degrees of it, but somehow he was afraid that for ever it would be the opinion of individuals. In the remarks he made at the last meeting he suggested that it would be really the happiest thing for them as regarded the question, particularly when they came to bring it into actual practice with regard to the examination of animals, if the public could be educated on the point. He was afraid that opinions governed all Veterinary Surgeons when they examined horses. Their opinions were based considerably on the public expectation or definition existing in the minds of the public as to what 'roaring' and 'whistling' was. He repeated the statement that he thought a good many horses were cast by Veterinary Surgeons because they were making some little deviations from what appeared to be normal, on the knowledge solely that the horse would come before someone else who would cast him, not because he had an unsoundness but in accordance with public custom.

He thought that Professor Craig had almost fully answered his own questions. He still thought they must describe 'roaring' or 'whistling' as any abnormal musical sound made in inspiration or expiration. He had often met horses making a noise in both. They might ride a horse which was absolutely sound, but if they got the head in a particular position the animal would appear very unsound, (hear, hear.) He had a horse at the present time which he hunted with the previous day, and if they took his head he would throw it up and become a 'gazer,' and would roar at once. If the head was dropped he would race away as sound as they liked. It was unnecessary to go into what were the symptoms. The younger men would always need to be put on their guard as to the kind of animal that he was speaking of—an animal that was sound and got his head into a particular position and became unsound. They all knew that some of the clever dealers would buy a horse and put a fellow on him who said he was making a noise, and they would get £20 or £38 off in consequence of the noise. The cause of the sound would be, as everyone had said, anything which interfered with the lumen of the larynx, or it being unable to allow the necessary amount of air to pass in. They would have to leave the pathology of the question with people like Professor Craig, who could spend more time than the ordinary practitioner could devote to it. With regard to heredity, no one would dispute that there was evidence to show that at least the pre-disposition was hereditary, and as to people not knowing whether an animal was ever born with the disease, it was going a little bit too far, because no one had ever had an opportunity of examining a foal, or even a yearling. He had seen foals which had become whistlers when they grew up. He had known sires bad roarers, and they bred 90 per cent that were sound. He had known a few sires perfectly sound that had bred 50 per cent unsound ones. If they went into the history of the animal, perhaps their predecessors were a little bit musical. Professor Craig has described the pre-disposing causes. Anything which was likely to have an effect either immediately or remotely on the larynx—colds, influenza, strangles, etc., which were likely to upset the larynx; all these might be looked upon as pre-disposing causes. He was convinced that none of these causes were sufficient, and were not responsible for a large percentage, and where they had an animal inclined to be sound and coming of a sound family, 90 per cent would recover, even from an attack of strangles.

With regard to the diseases from which 'roaring' and 'whistling' had to be differentiated, he had come across cases where mistakes might have been made. He went to examine a four-year-old colt last year, and put him in the lunge, and when he went round once or twice he thought the animal was a high blower.

His experience was that when a high blower got the nonsense taken out of him, the noise stopped. When he stopped this horse he was distressed, and the noise continued. He seemed to have complete paralysis of the right nostril. He thought possibly some nerve injury had occurred in hauling him along, as he was a bit wild but he saw him again in a month, and he was still bad. For 10 or 15 minutes after the exertion his lip was noticed to be pulled to one side. That was a case in which there might have been a serious mistake made. He might have been described as a roarer or a whistler, though from a cause independent of the larynx. He was not a roarer in the ordinary acceptance of the term.

The PRESIDENT: Did you trace him for any longer period after that?

Mr. HOWARD said he watched him, and even tried to buy him. He found that Mr. Parkinson at the Curragh had met a similar case, and he had cut the flap of the nostril, and the animal did all right. A lot of horses got it through being hauled about.

He took the opportunity within the last week of examining two horses operated on. One was absolutely sound except when his head was pulled. He had been called "Gramophone," and that would give them an idea how musical he was. The operation in his case had been a success, and there was no such thing as distress.

Mr. PATRICK: Is he sound?

Mr. HOWARD: No Veterinary could pass him as sound.

Mr. McKENNY said he would like to bet £50 that if a horse was distressed and Professor Hobday or anyone else operated on him he would be as bad afterwards.

Mr. HOWARD said that this horse was well-known in the show ring. He used to be considerably distressed. It was painful. He had seen that horse finish the previous day carrying 14 stone and he was as good as the best of them when they pulled up. There was a man present who would give £100 for him and he could not get him.

He knew a six-year old horse which was a bad roarer. They had him in harness and they could not let him do six miles an hour up-hill without being in a very unhappy state. He was a terrible roarer, and would become almost suffocated. But he made a considerable recovery, and he (Mr. Howard) used him all last spring. He was doing better than he could do before. Last April the animal went lame, and he turned him out for the summer. He took him in about a month ago, and when he came in he was giddy, and had to be put in the brake. The lads told him afterwards he was as noisy as ever, but he thought the fact was that coming off grass he was not fit, and perhaps got excited in the brake. At the present time he could do ten miles an hour, and Mr. McKenny would not know that he was making a noise. There was no distress now. Mr. Howard said he knew of other cases where improvements had been made although there was one mare which had not improved. All the others had done very well. The majority of them were bad grunTERS, but the harness horse was not a grunter.

Mr. PATRICK—That seems a common sequel to the operation.

Mr. HOWARD said he was surprised to hear Mr. Allen make a serious mistake about the term "bull." Among the horse world the term "bull" was used in reference to grunTERS, and not to noise. All bulls did not necessarily make noise.

Mr. DUNLOP said he had read, or glanced at Professor Craig's paper with much pleasure, and he did not think there was anything he had said that could be taken exception to. With regard to heredity he did not think that anyone ever alleged that a foal would be born with the disease, or have the disease before it was born. It is predisposition to roaring that is hereditary. The offspring of roarers are not invariably roarers but there is a general consensus of opinion that roaring is heredi-

tary. Scientists say that we only inherit about one-half of our peculiarities or characteristics from our immediate parents. As a general rule we inherit a quarter from grandparents and one-eighth from great-grandparents. They rarely found in families that there was an intermediate condition between their parents. Some times they found part of the family taking after the father, and another part after the mother. It was the same in the human subject as in the lower animals. It proved nothing whatever whether a particular horse had a sire or a dam which was a roarer. The general opinion was that it was hereditary. No one alleged however, that the foal was born a roarer. It was the condition that was hereditary. He could not agree with Mr. Allen that roaring in its regular form was caused by, or was the immediate consequence of stiffening or rigidity of the larynx. No doubt rigidity of the larynx does occur in some cases where the horse is very old or as a sequel to inflammation. Fifty-four years ago roaring was considered to be due to paralysis of the pneumogastric nerve or recurrent nerve, which led to atrophy of one of the arytenoid muscles. If the free edge of the arytenoid cartilage as a result inclined inwards, the air drawn in forcibly against its edge, it would vibrate, and the more rapidly the air was drawn in, it would tend to cause the cartilage to collapse more and the noise would increase. Not only would the opening be reduced, but the increased current of air would be a further cause of increased vibration. It was right that a young man should be taught to distinguish between high-blowing and roaring. So far as his experience went, high-blowing always took place during inspiration. It was more noticeable in horses that were nervous, particularly when going out on a cold morning. He always noticed in galloping that the moment the fore feet came to the ground this particular sound took place.

He had never known a case of genuine or regular form of roaring to be cured. He had known one case of a horse which was condemned by two Veterinary Surgeons and he was the third. He re-examined the horse when the case came on for trial, and found the horse was sound, so he had to turn against his own side.

Mr. PATRICK—Was anything done meanwhile?

Mr. DUNLOP—There was not. The late Mr. Farrell, 53 years ago passed a horse sound which all the Veterinary Surgeons in Dublin condemned as unsound as being a roarer. He was sent to Edinburgh. Professor Dick gave him a severe trial up a steep hill, and the horse made no noise and he was passed sound. He (the speaker) did not know much about roaring at that time, but he was then under the impression that the Dublin Veterinary Surgeons had forced the horse too much against the bridle until his head was in an unnatural position. I understand Mr. Farrell had put the horse to a severe test, so did Professor Dick. He fancied that sometimes Veterinary Surgeons and a great many dealers pulled the reins too tight and drove the horse against the bridle until the horse made a noise. He could understand that a horse with paralysis of the nostril would make a noise and that would constitute unsoundness while it lasted. He rather agreed with Mr. Howard that what was always known as a 'bull' was a 'grunter.' He always looked upon the 'bull' as a precursor to roaring.

Mr. WILKINSON said that a gentleman had stated that he had examined horses in shows and found them whistlers, and when they went before the referee they were not whistlers. Was that a usual occurrence?

Mr. HOWARD remarked that it was a common occurrence in shows that a horse would be a whistler in the morning and be passed before night.

Mr. PATRICK stated that he had known a horse that whistled to be passed as sound. They could often examine a horse and find him making a noise and later they would find him sound. He was gratified to hear

the remarks about the roaring operation. He had expressed the same opinion at Ballinasloe and was not agreed with.

Mr. HOWARD related a unique case of so-called spasm of the glottis. A mare at Galway last year had been working for some months, and nothing was known to be wrong with her. The mare was working on the tramway, and one day she got in a bad state on the journey to Salthill, and had to be taken out of the tram, and fell down from suffocation. They put her in and nursed her a-day or two and then they put her in the tram, and she went a hundred yards and then nearly suffocated. He put a lad on her back and had her jogged up and down the stable yard, and she did not go more than twice when she became very much distressed. Her neck did not appear like that of a 'roarer,' and he could scarcely give any opinion about her. He examined the heart and it seemed to be as sound as they could expect. He treated her with nerve tonics, and had her walked half-an-hour every day. The muscles of the larynx were massaged, and she was as sound as ever. He had seen her do a two mile gallop since.

Mr. PATRICK said he knew a similar case where a horse had actually to be tubed to prevent suffocation, and it recovered perfectly afterwards.

Mr. NORRIS said he knew two cases like Mr. Howard's of bad 'roarers.' One had a tube and the other went along all right. On one or two occasions he had a spasm.

(To be continued).

PERMANENT COMMISSION OF THE INTERNATIONAL VETERINARY CONGRESSES.

A Meeting of the above Commission was held at Baden Baden on the 4th June, 1911, the following members were present: Lydtin (President), Hutyra, M'Fadyen, Degive, Tuleff, Happich, Hess, von Ratz, Kjerrulf, Locusteau, Schimmel, Barrier, and de Jong, (Secretary).

The agenda for the meeting included the following:

(1) Minutes of the last meeting and report regarding the work of the Bureau.

(2) Information regarding the constitution of the Commission.

(3) Constitution of the Bureau.

(4) Communication of the views and resolutions of the Ninth Congress regarding the work of the Commission and of the Tenth Congress.

(5) Preparations for the Congress in London.

(6) Views and propositions of the members of the Commission.

The President in opening the proceedings mentioned that several members had wished a meeting of the Commission to be held the previous autumn, but the majority had preferred the period of Whit-Monday. In any case it was desirable to meet in 1911 in order to bring definitely to a close the work of the preceding Congress at The Hague. Actually more than a third of the members of the Commission were present, and therefore any resolutions arrived at by the meeting would be valid. The President mentioned the names of members who had excused their absence, and referred in feeling terms to the loss of two honorary members of the Congress, viz., Professor Robert Koch and M. Arloing. He added that, as he was himself ill at the time, he had invited M. Arloing to represent the Commission at the ceremony commemorative of Professor Koch which was held at Berlin in December 1910. Three months later M. Arloing, who was one of the Vice-Presidents, was himself removed by sudden death. In that case the President had represented the Commission at the funeral of their learned confrère.

At the jubilee of Professor Schütz, Professor Hutyra, the Vice-President, had been good enough to represent

the Commission, but unfortunately at the jubilee of Professor Dammann no member of the Bureau had been able to go to Hanover to represent them. The President had written to express the sympathy of the Commission with these celebrations.

In conclusion the President stated that in conformity with the statutes of the Commission he had been obliged to decline the request to organise an international congress on the occasion of the Congress of Hygiene at Dresden in 1911.

Passing to the agenda for the day, the President informed the meeting regarding the steps which had been taken in France in order to obtain a worthy successor to M. Arloing. Although the elections ought to be made by the future Congress, the Commission could make a provisional election, and the President was glad to say that M. Barrier was the candidate put forward by the French government and the French veterinary societies.

M. Barrier, having been elected by the Commission, received the congratulations of the President, and in returning thanks said that he would do everything in his power to further the work of the Commission. At the same time he conveyed to the meeting the salutations of M. Chauveau.

Before entering on the discussion of the second subject on the agenda for the day the President said that the Permanent Commission and the Executive Committee were two different bodies, and that it was not necessary that one person should hold the office of secretary to both, although, by an accident, that was the case at The Hague. A divergence of views between these two bodies did not signify an absence of collaboration. At The Hague the Executive Committee had collaborated with the Permanent Commission, and it was the right and the duty of the latter to offer useful criticism. He wished once more to take cognisance of the fact that at The Hague very valuable work had been done in the interests of the profession and of science. What had been done in that connection by the organisers of the Congress merited praise, and he took the opportunity to offer their thanks to MM. Schimmel and de Jong.

M. Schimmel thanked the Commission and also the President and Secretary.

M. de Jong also returned thanks, more especially to the President, who had always seconded his efforts in very difficult circumstances.

The Secretary read the list of the members of the Commission.

On the proposal of the President the third subject on the agenda for the day, viz., the election of the Bureau, was postponed until the afternoon sitting, and the Commission proceeded to consider the fourth subject, viz. the views and resolutions of the Ninth Congress. According to one of these resolutions the Commission had to consider the question of establishing an International Commission for dealing with tuberculosis in animals and eventually to formulate a proposal to the next Congress. The meeting thought it desirable to nominate a reporter to study the question, such reporter to have the right to confer with different specialists. M. de Jong was nominated reporter on the subject.

With regard to the Resolution Section I., III., 9, (disinfection of railway wagons), it was decided to appoint as a committee to consider the subject MM. Hess, Schnürer, and Ostertag, and M. Martel if M. Ostertag did not accept. The report of the meeting of the committee to be presented to the Congress in London.

Resolution Section V., II., (regulations regarding over-sea transport of animals). The meeting appointed as a committee MM. Stockman, Rickmann, Hoogkamer, and van Es.

It was decided that the invitations to join these committees should be sent by the Secretary in the name of the President.

The other opinions and resolutions of the Ninth Congress which had a special interest for the Commission or for the future Congress had already been given effect to or they will appear in the programme of the Congress in London.

The President read a telegram from M. Piot excusing his absence, and another from the French Minister of The Hague announcing the name of M. Barrier as the French delegate.

At the afternoon sitting of the Commission the first business considered was the election of the Bureau. M. Lydtin, the President, intimated that on account of his age and the state of his health he did not wish to be proposed as a candidate. M. Degive, however, asserted that he was interpreting the views of all present in saying that it would be in the interests of the Congress and of the Commission to re-elect with unanimity their venerated and very active President. In view of the general applause with which this proposal was greeted, M. Lydtin agreed to accept the office of President, and thanked the members for their confidence.

M. Lydtin proposed as Vice-President M. Hutyra, who had already held this office, and whom he designated as his future successor. This was carried unanimously, and M. Hutyra returned thanks. The President had thought of M. Bang as second Vice-President in place of the late M. Arloing, but as M. Bang did not attend the meetings of the Commission he said that M. Degive appeared to be a very suitable candidate, and that perhaps M. Barrier, being French, was still better qualified to succeed M. Arloing. M. Degive advocated the election of M. Barrier, but the latter, while expressing his warm acknowledgments, said that he was the junior member, and M. Degive had the greater right to the office and would be a worthy Vice-President. He therefore proposed M. Degive, and this was carried unanimously.

M. de Jong was selected as Secretary, and M. von Ratz as Joint Secretary and Treasurer. Both of these gentlemen returned their thanks for the honour.

The President then called on Sir John M'Fadyean, who said that certain provisional arrangements with regard to the holding of the next Congress in London had already been made, and that it was his intention to have a meeting called at an early date at the Royal College of Veterinary Surgeons. The question of financing the Congress had been the subject of consideration, and it appeared probable that they would be able to raise the necessary funds. It was their intention to choose the subjects to be discussed at the Congress with every care, and in that connection they would bear in mind the suggestion made by M. Hutyra. He desired to ascertain the views of the Commission as to what would be the most convenient time for holding the Congress. He suggested that the last week in July, which formed the close of the London season, would be the best, or alternatively, the first week in August. He thought that the month of September would be too late. With regard to the funds necessary to carry through the work of the Congress, he mentioned that they would not receive any Government subsidy, but, on the other hand, he believed that the members of the profession in Great Britain would subscribe liberally. The Commission resolved to fix provisionally the date of the Tenth Congress for the end of July or the beginning of August 1914, and the President thanked Sir John M'Fadyean for the information which he had given them.

The President then called on M. de Jong, who wished to raise a question of much importance.

The accounts of The Hague Congress would probably show a surplus of about 2,500 Dutch florins as a result which was due to an extraordinary subsidy which the Dutch Government had given to the Executive Committee, fearing that the ordinary grant would be insufficient. The idea had occurred to the Executive Committee at The Hague to take the necessary steps in order

that this sum might be available for the Permanent Commission, and more especially for the Secretariat. The latter might be fixed at The Hague, following the example of the Permanent Commission of the International Medical Congresses. The Hague was becoming more and more the seat of international corporations, and it seemed to be in the interests of the organisation of the Permanent Commission and of the International Congresses that the Secretariat and the archives should be located in some definite office and place. If the Government of The Netherlands were disposed to favour the idea of obtaining an office at The Hague, and at the same time the functions of a Secretariat, the Executive Committee of the Congress would probably have handed to them the surplus of 2,500 florins to be employed in paying the first cost of the installation of the Secretariat. All that would be in the interests of the Commission, which would then have obtained a special office for its Secretariat, while the latter would possess its own proper premises under the patronage of the Dutch Minister of Agriculture.

In reality, the Netherlands Minister of Agriculture was disposed to favour the idea, and he had authorised M. de Jong to say that if the Secretariat of the Permanent Commission were installed at The Hague His Excellency would give his patronage to it, and also to the meetings of the Commission in the event of these being sometimes held at The Hague. Subject to the same conditions, the Executive Committee of the Congress would place the sum of 2,500 florins at the disposal of the Permanent Commission.

The Minister would also put at the disposal of the Commission an office in which would be deposited its archives and its library, and in case of any meetings of the Commission being held at The Hague the necessary accommodation would also be provided. The Minister would also extend his patronage to the correspondence of the Commission if the latter required his support. But, apart from such support, the Commission would remain independent in its divisions and movements.

Unfortunately, although the initial proceedings in the matter had been taken some months previously, His Excellency's letter was not received until the 31st May, and thus had only been in possession of the Secretary for four days. There was therefore absolutely no time to have the question placed on the agenda. That, however, did not appear to be indispensable, in view of Article 13 of the Statutes of the Commission, which allowed them to consider propositions which were not included in the programme of the meeting provided they receive the support of a third of the members present. The Secretary stated that he had that day communicated his idea on the subject to the President, and as a result of the conversation he had the honour to move the following propositions:—

(1) That the Permanent Commission approve of the formation of a Secretariat as a permanent institution, possessing its own office and funds, and, if necessary, its own staff.

(2) That the Commission accept the offer of the Executive Committee of The Hague Congress to employ the surplus from the Ninth Congress for the installation of the Secretariat at The Hague.

(3) That, subject to the approval of the Governments who have sent delegates to the Commission, the Commission accept the offer of the Minister of Agriculture for the Netherlands to patronise the installation of the Secretariat at The Hague, especially in the interests of international correspondence.

M. Barrier enquired whether in accepting the proposition the Commission would remain independent, and if the funds necessary for the correspondence would be at the disposal of the Commission. M. de Jong replied in the affirmative.

M. Hutyra, while recognising the advantages of the

proposition, thought that they could not deal with the matter since it had not been put on the agenda for the meeting. They had to consider three questions: (1) Whether it was necessary for the Commission to have a fixed office; (2) if so, in what town; and (3) if the Government who had sent delegates to the Commission would be in favour of the proposition. He himself had no authority from his Government on the question, and therefore he could not vote on the matter. He begged the Dutch delegates, in the first instance, to circulate their proposition to all the members of the Commission, after which the matter could be discussed.

In the course of the discussion which followed, MM. Hess, Kjerrulf, and M'Fadyean said that they also had no power to vote on the proposal, as they had received no definite mandate from their Government. M. Degive said that he was not quite clear as to what would be the consequences of the proposition.

The President then put to the vote the question: "Is there any opposition to the formation of a fixed Secretariat?" The result was that seven members voted for a fixed Secretariat, four against it, and two members did not vote. M. Hutya then brought forward his proposal that the question should not be considered until after notice had been given to all the members of the Commission. This motion was rejected—six voting for and seven against it. The President then put separately to the vote the three parts of the proposal of M. de Jong, with the following results:—

The first part was accepted by seven votes and six abstentions.

The second part was accepted by six votes and seven abstentions.

The third part was accepted by seven votes and six abstentions.

Thus the whole of the proposal was carried. Several of those who had abstained from voting declared that personally they were in favour of the proposal.

The programme of the meeting being now exhausted, the President thanked the members for their attendance, and the sitting came to a close after M. Barrier, on behalf of the members, had in very cordial terms thanked the President for his services in the chair.

DR. LYDTIN, *President*.

D. A. DE JONG, *Secretary*.

Veterinary Science—An Appeal.

In 1790 the Odiham Society of Agriculture in Hampshire appointed a committee "to consider the best method of improving the art commonly called Farriery," and during the following year founded the Royal Veterinary College, which acquired its present site at Camden Town in 1792, when the first students were enrolled. The fees were fixed at twenty guineas for the sessional year, and have remained at that figure ever since. At the commencement of its existence, the College had to rely on donations and subscriptions, supplemented by the small amount of students' fees, for the acquisition of a site, building operations, and the remuneration of the staff. But in 1795 Parliament, in recognition of the national character of what was being done, made an annual grant of £1500, which, however, was withdrawn in 1815, and no further State aid was given until 1906. During the first half of the last century the College discharged the double function of a teaching and an examining body; but in 1844 an agitation arose amongst veterinary surgeons, and they were incorporated by charter as the Royal College of Veterinary Surgeons. That College is still often confounded with the Royal Veterinary College, to which it really stands in much the same relation as the Royal College of Surgeons does to the different hospitals. It fixes the terms and standard of veterinary education, and prescribes the period of study, but is not itself a teaching body: it conducts the

examinations and grants the veterinary diploma, thus holding the door of admission to the whole profession, and being in fact the only portal through which the veterinary surgeon can pass. In 1881 the Veterinary Surgeons Act, which is somewhat similar to the Medical Act, was passed, making it an offence for any one to call himself a veterinary surgeon without the diploma. The amount of knowledge required to pass these examinations represents merely the *minimum* attainments considered necessary for those who are to engage in veterinary practice: and the Royal Veterinary College has constantly had to extend its operations.

In an endeavour to meet the new requirements the Governors between the years 1890 and 1894 spent nearly the whole of the accumulated funds of the College (about £13,000) in building and equipment, while the teaching staff has been gradually increased until it now numbers nine professors and five qualified assistants. The course of instruction covers four years, and students are prepared for the degrees of Bachelor of Science and Doctor of Science and Veterinary Science at London University. This has entailed considerable additional expense, and, if the work of the College had to be curtailed, the preparation of students for these degrees would be the first thing to be given up. There is also a Post-graduate course in veterinary pathology and bacteriology, with an average attendance of 40 students during the past five years. This is one of the most important services rendered by the College, and, had it not undertaken it, the standard of veterinary science in Great Britain must necessarily have been much lower than it is at present. The course, moreover, is of particular value in qualifying men for the Colonies.

THE PRESENT POSITION.

Unfortunately the position of the College to-day is somewhat critical. It depends entirely upon voluntary subscriptions or donations, an annual grant of £500 towards the expenses of the Department of Comparative Pathology and Bacteriology, and a grant of £1300 a year from the Board of Agriculture. The grant of £1390 from the Development Fund is ear-marked for the expenses incurred in experiments and not for remuneration, mainly in vaccination with relation to tuberculosis, and has imposed extra work upon the staff. Sir John M'Fadyean, the Principal, having himself frequently to travel about the country in connection with experiments. It is impossible to raise the fees, as the students are the sons of men of very moderate means, and the number of students is tending to decrease. The prospects of the profession are not nearly so good as they were a few years ago, owing to the introduction of motors, and the consequent diminished demand for horses, whose treatment constituted the most profitable part of a veterinary surgeon's practice. An appeal to the Government is therefore imperative, and their attitude compares most unfavourably with that of the Government in other countries. In Prussia, for instance, the State expended £12,000 upon building a veterinary college, and makes an annual grant of £5,600; in Saxony £90,000 was spent on building, and the annual grant is £6,400; in Bavaria £57,000 on buildings, with an annual grant of £10,000; in Hanover £150,000 for buildings, and the annual grant is £3,650; in Wurtemberg £36,000 on building, and a grant of £4,550; in Holland the Veterinary College at Utrecht has an annual grant from the Government of £7,125. The indifference of the present Government to England and Wales is all the more remarkable in view of the substantial assistance already given to Scotland and Ireland. Under Section 16 (1) (a) of the Agriculture and Technical Instruction (Ireland) Act of 1899, a sum of £15,000 was applied for the purpose of providing suitable buildings, fittings, and appliances for the Royal Veterinary College at Ballsbridge. This sum was supplemented by a fur-

ther grant of £12,350 from the endowment fund of the Irish Department of Agriculture.

With regard to Scotland, £5,000 has already been given as a capital grant to the College in Glasgow, and £20,000 is to be given to the Royal (Dick) Veterinary College in Edinburgh. It is probable also that both Colleges will be assisted by the Development Fund.

For this differentiation in the aid given to particular parts of the British Empire there is absolutely no justification. The public here, moreover, hardly yet realise the supreme importance of veterinary science. The veterinary profession is the servant of agriculture, and it is essential to the welfare of agriculture that it should be composed of men as thoroughly educated as possible. But it is not merely in the industrial and commercial interests of the stockbreeder, the farmer, and the small holder that this is necessary. The health of the whole community depends upon the elimination of all risk of its contracting disease from animals, and upon the quality of the food which it consumes. Protection in both of these directions can alone be secured by means of veterinary knowledge. New problems are constantly cropping up; and it may safely be asserted that there is no disease affecting animals which does not stand in need of further investigation. This is the indispensable antecedent to all preventive and remedial measures.

It is true that we have not, and are never likely to have, complete and absolute knowledge of the pathology of any disease; but science can enable man to control most diseases, even if they are not wholly eradicated. Scientific investigation has, for example, caused outbreaks of glanders to be substantially decreased during recent years by the mallein test. On the other hand, there has been a very decided increase in the numbers of outbreaks of anthrax.

All this points to the urgent necessity for more systematic inquiry. The ground to be covered is too vast for the machinery that exists at present. We still know very little about anaemia in sheep, as is evidenced by recent correspondence in *The Times*. Is the disease due to a minute threadworm, or anaemia pure and simple? Is the emaciation caused by anaemia or by parasites? The disease, too, which was first described by Johnie, and is named after him, has lately received a good deal of attention in various parts of the world. It is a chronic inflammation affecting the internal coats of the intestine (enteritis) in cattle, and was first discovered in England by Sir John McFadyen about five years ago. Much more intimate knowledge of the pathology of this disease, both by experiment and field observation, is needed to ascertain how far affected animals react to tuberculin prepared with the bacillus of Avian tuberculosis. Again, it is impossible to eradicate a disease like sheep-scab without closely studying its epizootiology. It is not until a campaign of eradication has been undertaken that the veterinary surgeon can determine what seem to be errors or insufficiencies in the classical parasite, the development of the disease, and the effect of remedies. No expenditure can be deemed too great to ensure immunity from these various diseases.

Much doubtless can be effected by the judicious expenditure of the £50,000 per annum out of the Development Grant but this is to be applied solely to various forms of agricultural research. The Board of Agriculture has already determined the eleven subjects for which the grants are to be made, and there is nothing to indicate what sums will be available for veterinary science. In any event it seems impossible for the Royal Veterinary College to receive any aid towards building or maintenance.

THE URGENT NEED.

The fact has to be faced that veterinary education cannot be self-supporting. The Royal Veterinary Col-

lege has reached the limit of its resources. There is an increased demand for Veterinary Surgeons in connection with the Diseases of Animals Acts, but it is not easy to see where they are to be obtained. It has become increasingly difficult to satisfy the needs of the country, besides providing for the Colonies, where the best veterinary work has been done by men trained at the College. The whole economic and industrial development of the Protectorates in Africa will depend upon the supply of men qualified to control or subjugate the diseases of animals there. Nor must the requirements of the Army be overlooked. All military veterinary surgeons have to study at one of the veterinary colleges, after which they receive a little special training in the particular duties pertaining to the Army. Mention should also be made of the out-patients' clinique at the Royal Veterinary College, which does so much by way of advice or treatment for the poor owners of horses or donkeys. In the course of last year 4,855 individual cases were brought to the College, and, as several of these had to pay more than one visit, the total number of inspections amounted to 6,970. In the Research Laboratory, towards the expenses of which the Royal Agricultural Society are giving a grant of £200 for three years, there were complete or partial post-mortem examinations of 688 animals, while 952 animals were under treatment in the infirmary.

These figures illustrate the manifold activities of the College. If veterinary education is to attain the standard which it has already attained in most countries, it is absolutely necessary for the Government to aid it upon the same scale as do other Governments. It would be a national disgrace if there were no continuous advance in veterinary knowledge here, and we had to depend upon the research and experiments of Continental veterinary colleges. — *The Times*.

The Protection of Animals Act.

The Protection of Animals Act, 1911, which was introduced in the House of Commons by Mr. George Greenwood, a member of the Council of the Society for the Prevention of Cruelty to Animals, came into force on January 1st.

The Act was drafted by the Society, with the assistance of Mr. Greenwood and the Rev. the Hon. W. E. Bowen. It consolidates the statutes which deal with cruelty to animals, and contains many amendments which have been proved to be necessary. The measure relates to both domestic and captive animals. It will be an offence in future cruelly to beat, kick, ill-treat, over-ride, over-drive, overload, torture, infuriate, or terrify any animal or to cause or permit any of these acts to be committed. The *maximum* fine is increased from £5 to £25, and the imprisonment, which may be alternate or additional to the fine, is increased from three months to six months, with or without hard labour. Owners who by failing to exercise reasonable care and supervision permit any unnecessary suffering to an animal are liable upon conviction to a fine of £25.

The Court may order the destruction of an animal, when the owner is convicted of cruelty, on being satisfied that it would be cruel to keep the animal alive. The Court, when convicting the owner, may, upon proof of a previous conviction or upon evidence that further cruelty may be inflicted, deprive him of the possession of the animal. This last amendment is due to the National Canine Defence League, and was moved by Lord Leigh, when the Bill was in the House of Lords.

The Act contains a set of regulations to be observed by knackers all over the country. In these regulations it is laid down that the slaughter of all animals disposed of to a knacker must be carried out within two days; that children under 16 years of age shall not be allowed in the slaughter yards, and that no animal must be

killed in sight of another animal. A clause in the Act also provides that no knacker may act as a horse dealer. This is an important provision, for it prevents horses which have been sold for slaughter from being disposed of for draught or other purposes.

It is provided that steel traps set for hares and rabbits shall be inspected at reasonable intervals, and at least once a day between sunrise and sunset. Employers are compelled to produce employees against whom proceedings are taken, and also to produce the animal which is the subject of a charge of cruelty. Power is given to the Court to forbid the sale of, or parting with, an animal pending the determination of an appeal from a conviction, and the definition clauses are considerably extended in respect of all domestic and captive animals. The period within which proceedings may be taken has been extended from one month to six months.

The Act does not apply to Scotland.

Personal.

At a general meeting of the Council of the County Borough of Stoke-on-Trent, held on Thursday, Dec. 21st last, Prof. W. T. WILSON, F.R.C.V.S., Member Royal Sanitary Institute, was appointed to visit and examine all the cows and cowsheds within the County Borough, with special regard to tuberculosis of the udder, and to examine microscopically all suspicious milk.

ARMY VETERINARY SERVICE.

WAR OFFICE, WHITEHALL, Jan. 2.

Lieut. E. C. Doyle has been transferred from Colchester to Norwich.

The following officers embarked at Southampton on 3rd January, 1912, in Transport "Rohilla" for a tour of service in India:—

Captains E. C. Orton, W. A. Jelbart, R. C. Matthews, W. M. Millar, W. Ludgate, R. Porteous.

"PUPPY WORM CAPSULES."

Sir,

I should be much obliged if you would bring before the notice of the profession a type-written letter and sample of pills which I believe has been sent by a certain quack medicine firm to a great number of members of the profession. I have received this letter and a sample of pills. Their excuse for sending them highly amused me. They state: "We offer them at the low price of 15s per thousand; our reason for so doing being that owing to a misunderstanding 100,000 of these capsules were made of the wrong shape, so that we are unable to make use of them in the ordinary course of our business."

May I ask, is the veterinary profession going to be made a receptacle for their cast-off rubbish? Are we going to prescribe patent medicines, not knowing their contents? Are we to believe that this is not one of the common up-to-date advertising tricks, which are so common nowadays? I consider the latter part of the letter confirms this idea.

Yours truly, JAS. T. ANGIN.

Arundel, Sussex. Dec. 21.

"Dear sir,

We are taking the liberty of sending you under separate cover a sample of Puppy Worm Capsules, and should esteem it a favour if you would give them a trial in your practice.

We guarantee them perfectly safe to give to the smallest and most delicate puppy, and you will find them most effective.

We offer them at the low price of 15s per thousand, our reason for so doing being that owing to a misunderstanding 100,000 of these capsules were made of the wrong shape, so that we are unable to make use of them in the ordinary course of our business.

Should you find them satisfactory in every respect, as we are confident you will, and decide to use them, we undertake to supply your future requirements of these capsules at the same price as we now offer them."

PRACTICES FOR DISPOSAL

MIDLANDS. Receipts average £1400 per annum. Present hands over 30 years. Exceptionally good premises, rent £85. Working expenses very light. Easily worked. Fees good. Valuable appointments. Capital required about £1400, including valuation. Good introduction given.

WESTERN COUNTY. Receipts about £600 per annum. In present hands nearly 50 years. Advancing age sole reason for sale.

PURCHASERS ARE REQUESTED to call, or write stating their requirements, as we have numerous Practices on our Register which have not been advertised. *No charge* is made to purchasers.

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

PROSPECTUS, containing "*Hints to Vendors*" and "*Hints to Purchasers*," post free on application.

To Vendors.

WE make no charge unless a Sale is effected. If you have a genuine Practice you wish to sell quickly and without publicity we shall be please to place particulars on our Register.

"MAGNUM" PESSARIES.

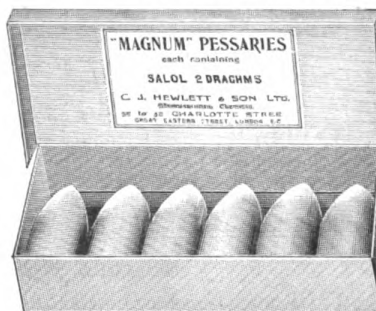

(HEWLETT'S)

"Magnum" Pessaries are prepared with a medicated non-oily base which is both effective as a Uterine Antiseptic and of special benefit in Parturition both in Cows and Mares.

A "Magnum" Pessary should be inserted directly after parturition in order to maintain the Uterus in a healthy state. It can be inserted with the greatest ease and will keep the parts in a thoroughly antiseptic condition for a lengthy period.

Alkaline "Magnum" Pessaries have recently been recommended to neutralise excessive acidity of Vaginal secretion.

"Magnum" Pessaries are supplied according to various formulæ as below, and Veterinary Surgeons' own formulæ can be made up as required.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1227.

JANUARY 13, 1912.

VOL. XXIV.

CANINE TUBERCULOSIS.

In a recent number we published a carefully described clinical and post-mortem observation upon canine tuberculosis by Mr. Wallis Hoare—the second record of the nature which the same pen has given us during this year just closed. As we have said before, the subject deserves more attention than most practitioners have yet given it.

Various reasons favour the view that canine tuberculosis is more common than is realised. We may mention two in particular—the undoubted fact that the disease in dogs, as in other animals, often proceeds to an advanced stage without causing noticeable symptoms; and the frequent neglect by practitioners of their opportunities for post-mortem observation. Mr. Hoare remarks that some owners object to autopsies, and this is quite true. But many more autopsies than are made might be made, especially upon animals dying in veterinary infirmaries, if practitioners would utilise their opportunities. Very few do so fully—many neglect them woefully—and the state of our knowledge of canine tuberculosis is one illustration of the results. There is good reason to suspect that many dogs die of conditions such as pleurisy and ascites, supposedly sporadic in origin, which an autopsy would have revealed as tubercular.

The recently instituted compulsory notification of human tuberculosis will probably lead to a more systematic and comprehensive enquiry into the sources of infection in man than has yet been instituted. Canine tuberculosis will fall within the scope of that enquiry. Is our profession now in a position to render any great assistance in it? And yet a few members, each possessed of a good canine practice and rigidly observing the rule “A post-mortem whenever possible,” might be able to render very valuable assistance.

A NEW VETERINARY ASSOCIATION.

With the reconstituted National promising to take up its enlarged sphere in the present year, the advent of this new Association—the second in the course of a few months—we may hope is an augury of increasing activity in the internal life of the profession.

It is beyond question that these societies are a power amongst us which makes strongly for cohesion—for unity of thought and of action. Powerful as the press is in leading to assimilation of thought, it has not the cementing qualities of these personal meetings. And although the published minutes of the Societies may correctly represent the business of the meetings and the discussions, usually there are other matters mentioned at the

meetings which are of sufficient importance to make it worth while to be present, and besides, most of us can recall occasions on which we have picked up some hint, direct or suggestive, on matters clinical which has proved of value.

The one possible objection to a new Society—that it may overlap and weaken its next neighbours—can scarcely exist in this case, from geographical considerations, since its only land boundary—on the west—would seem to be the railway from London to Brighton, and Brighton may reasonably be looked upon as the most easterly meeting place of the Southern Counties, and might well form a joint meeting place for the two Societies once a year.

Kent has, according to our Register, just on sixty practising members, it has good railway centres—Canterbury, Maidstone, Ashford, Tonbridge, besides attractive coast towns; and in its southern half a large animal population. The remaining factor, and the important one—membership—looks promising, since forty favourable replies were announced at the first meeting, and what may be lost to London on the north may be made up from East Sussex, and possibly from Surrey, since Redhill and Reigate are as near to Tonbridge as to London.

To those men who may still be doubting about joining a Society, and to those Societies who still hesitate at the *per capita* affiliation fee for combination, we would say, in the vernacular, “You can always get nothing for nothing.”

DO WHISTLING AND ROARING DEPEND ON SIMILAR PATHOLOGICAL CONDITIONS?

By E. WALLIS HOARE, F.R.C.V.S.

If we refer to text-books for an answer to the above query we find considerable differences of opinion.

WILLIAMS (“Veterinary medicine”) states “that whistling and roaring are due to different pathological conditions of the larynx and they may exist independently of each other.” He regards whistling as “due to a diminution of the calibre of the larynx, or sometimes trachea, owing to a permanent thickening of the mucous membrane, distortion of the neck by tight reining, the presence of an immovable tumour in the trachea, or by any cause which diminishes the area of the passage of the air to and from the lungs.”

ROBERTSON (“Equine Medicine”) describes both affections together, and states, “under the general term of ‘roaring,’ we are inclined to group all

those abnormal sounds emitted by horses under exertion, and known as roaring and whistling, not because we regard them as in every case but modifications as to severity of intensity of one and the same sound, but merely because they are all deviations in the matter of sound from the condition of normal respiration."

Later on he observes "In actual practice, however, we meet with many instances of horses which are what is universally recognised as "whistlers" which have not passed through the stage of "roaring," and many so-called "roarers" which have steadily advanced from one degree of roaring to another, without ultimately terminating as "whistlers."

PERCIVAL ("Hippo-pathology") regarded whistling as a more advanced state of roaring, basing his conclusion on experiments which he made by means of a ligature passed around the trachea; when the calibre of the trachea was moderately diminished roaring was produced, but a further diminution caused whistling.

It does certainly seem peculiar that in the case of so common a condition as whistling, pathological investigation has not yet succeeded in ascertaining the exact lesions on which the abnormal sound depends. Further evidence is necessary before accepting the statement that whistling and roaring should be regarded as identical conditions, the variations in the sounds depending on modifications of certain abnormal states of the larynx and other structures.

Whilst admitting that the border line between well-marked cases of whistling and the condition known as roaring is often difficult to define, and also that a large number of whistlers ultimately become roarers, there are some facts on the other side which cannot be ignored.

It is well-known to horsemen as well as to veterinary surgeons, that a large number of horses become whistlers, are able to do their work, and continue in that condition for the remainder of their lives.

Now can this be said in the case of roarers? Would anyone have the temerity to advise the purchase of a roarer, knowing full well that the disease is so often progressive in its nature?

If whistling always terminated in roaring what an enormous number of roarers would be found in a country like Ireland, where whistlers are so common that the defect is responsible for the rejection of more horses, than any other condition.

If the new operation for roaring proves successful for the cure of whistling, that result would not prove that the two conditions are similar, for, granting that whistling depends on a permanent thickening of the laryngeal mucous membrane, the operation increases the calibre of the larynx and should benefit the case.

But is there any actual proof that whistling depends on this alteration of the laryngeal mucous membrane? Has it been demonstrated by post-mortem examination? Or have the laryngeal lesions found in many cases of roaring ever been discovered in cases of whistling?

These matters should be decided before we venture to assert that the views expressed by Williams are erroneous, or that the usual opinions held by horse owners on the subject, and by many veterinary surgeons, require to be modified.

Surely an examination of the larynx in a large number of cases of whistlers would at any rate decide the question so far as alterations in the laryngeal mucous membrane are concerned.

But whistling, so far as its pathology is concerned, is in very much a similar state to that of other common conditions in veterinary practice. Take for example that very common disease known as curb. Have we advanced an iota in our knowledge of its pathology since the days of Percival? Percival made many dissections and examinations of hocks affected with curb, and showed that the views held concerning it were erroneous, yet at the present day the disease is regarded by the majority of authors as strain of the calcaneo-cuboid ligament. Probably when the subject is again investigated, it will be found that under the heading of curb more conditions than one exist.

And so it is with many other diseases met with in every-day practice; if they are regarded as incurable, the interest in them is inclined to vanish, or if the cure is discovered a similar state of affairs comes to pass. No doubt the commercial aspect exerts a marked influence on the apathy with which such affections are generally regarded.

One important matter has been elicited by recent discussions on whistling and roaring—the occasional intermittent character of these affections. This may have the effect of explaining to the public how it is that a horse may be examined by one V.S. and rejected for his wind, and passed as sound by another, or *vice versa*. At present, when such occurs, either one practitioner or the other is designated as ignorant, according to the parties affected in the transaction. It may also show that the soundness or otherwise of a horse's wind is simply a question of opinion, and that differences of opinion may, and will, occur in matters of this kind.

As to those nice discriminations between whistling and other sounds not attributable to this condition, I am of opinion that in our present state of knowledge, and with the means of diagnosis we possess, the fact of a horse making an abnormal respiratory sound—whatever term we wish to apply to it—legally compels us to inform the purchaser. Of course I am not referring to "high-blowing," which, as the veriest neophyte knows, is not a cause of unsoundness.

In connection with roaring, it is interesting to note that Robertson stated that "the position of the head and neck materially affects the production of the sound in some cases. An animal reined in for the canter may whistle or roar, while with the head free in the gallop, the slightest abnormal sound may not be detected. It is consequently advisable to always examine horses with a snaffle and curb, as in the one the animal may roar, while in the other no abnormal sound is emitted." Now this statement is one with which many practitioners will not agree, and the question arises whether it

is a fair test or otherwise. Surely if the horse is unsound of his wind the defect will be ascertained when he is galloped and subjected to exertion. Moreover, it is well known that perfectly sound horses may "make a noise" if the head and neck are kept in the abnormal condition indicated, especially if the rider has not "good hands."

The foregoing remarks are made with a view to eliciting information. Being in the unfortunate dilemma of having to write a section on "Whistling and Roaring" for the "System of Veterinary Medicine" which I am editing, I shall welcome any criticism or suggestions on the subject. My queries on a former occasion were so ably responded to, and proved of such marked assistance, that I venture to hope for similar help in this instance.

THE WAY OF THE WARBLE.

One is taught that the *Hypoderma Bovis* lays eggs which develop into larvæ under the skin of the back, and one is left to imagine how, when, and why this transformation takes place. Perhaps it would not be impertinent to ask the following questions, and to add here and there one's own comments on things as they are found sometimes.

Why do observers say that the first stage of larval development has not been seen, and then stultify their remark by saying that the larvæ have been seen leaving the egg in the œsophagus of their host?

Now the female fly is acknowledged to lay her eggs upon the hair in a similar way to her congener who affects the horse, and not to deposit them under the skin; and it is supposed that the larvæ get in through the sweat or sebaceous glands. Why this supposition? It is comparatively easy to catch them, *in flagrante delicto* if they do, but no one has done so. On the other hand they have been found leaving the egg in the œsophagus, and at a later stage they have been found wandering in the pleura, and among the costal muscles, and in the subcutaneous connective tissue of the sides and back.

Their mode of exit from the back is generally acknowledged to be a form of ulceration or necrosis commencing on the inner surface of the skin, and not to be a hole from the outside, which it ought to be, if it commences at the supposed point of entry. This being so, is it not probable that the intruder has arrived from the inside rather than from the out?

The subcutaneous damaged condition is spoken of as "licked beef," but as a matter of fact a good deal more licking takes place in other localities than directly over the back, and one does not find the peculiar condition in these places unless now and again one finds a solitary warble, which is looked upon as rather a freak for not being upon the back, while statistics show that this is by no means an uncommon occurrence, and where these warbles are there is an area that is "licked." Is this only a coincidence, or a case of cause and effect?

Next, take a typical warble and examine the seat of the larva, and in the majority of cases one will find leading away from this spot a direct tunnel through the connective tissue, generally tending downwards towards the sides rather than along the back, a tunnel that an ordinary probe can easily enter and follow for some little distance, when it becomes gradually obliterated. Is this the road by which the wanderer has been seeking his pole?

One knows of numerous instances of other parasites who select their abodes by a special selective faculty, and which are found in various stages of development on the journey to their eventual resting place. Is not one justified in applying a little common-sense and logical reasoning to the warble?

And one offers these points for consideration:—The larva is not found on the hair in its early stages; it is found in the œsophagus and pleura and subcutaneous connective tissue of the host, both in the earliest and succeeding stages; and where it is found in its later stages it is accompanied by a definite pathological condition of the tissues surrounding it, and by a very suggestive condition, namely, the tunnel.

Considering these facts one feels justified in agreeing with certain American and Continental observers in their hypothesis that the larvæ reach the back *via* the œsophagus, and not through the skin. But one would like a sufficiency of corroborative observations from others before laying down the law.

F. E. P.

DISLOCATION OF THE CERVICAL VERTEBRÆ.

Subject.—A six-year-old bay cart mare. I was called to see her at 7 a.m. on Dec. 26th, because she was unable to get up when the team man found her in the morning.

Symptoms.—I found her decidedly tympanitic, anus and vulva greatly swollen, apparently suffering great pain, sweating profusely, and showing no sense of feeling when her limbs pricked with a pin. The pulse was very fast, and difficult to take, and the temperature impossible to take owing to swelled condition of anus and vulva.

Prognosis.—Decidedly unfavourable.

Treatment.—I decided to put slings under her to see if she could stand when once pulled up on to her feet. As is usual in these cases, we had to have two or three men pulling on her tail, and an equal number on her head before getting her into a suitable position for slinging. When all was ready we began to pull her up, but directly she was raised about a foot from the ground her head dropped suddenly and she expired directly.

Post-mortem. The mere fact of her dying so suddenly made me suspect some unusual trouble, and as I was unable to make a post-mortem myself I left word for the slaughterer (a very skilful man at his trade) to send me the result of what he found. To my surprise he reported that the mare had complete dislocation of the 3rd and 4th cervical verte-

bræ, attended with great inflammation of all the muscles of the neck.

Remarks.—Undoubtedly the mare had cast herself in her box, so dislocating the cervical vertebrae and setting up symptoms of paralysis. Although I had allowed three men to pull her round by the head, the spinal cord did not sever until we began to sling her, when the weight of the head completed the dislocation.

W. WATERS, M.R.C.V.S.

Blofield, Norwich.

VETERINARY MEDICAL ASSOCIATION OF IRELAND.

ROARING AND WHISTLING.

[Adjourned discussion on Prof. Craig's paper.]

(Continued from page 436.)

THE PRESIDENT said he thought they should congratulate themselves on the paper they had had from Prof. Craig and also on the discussion it had aroused, not only on the previous occasion, but that evening. It was satisfactory to get the opinions and experiences of gentlemen in general practice. He was not a practitioner, and consequently had nothing to add to the discussion. He was only interested in the question from the point of view of pathology. He did not know that he could throw much more light upon it than had been done by other investigators.

He might mention, however, the result of an examination that they made into a 'roarer.' It was an examination they carried as far as possible in this particular animal. The investigations were not entirely completed, but some of the results they had were rather interesting. In the first place they found, Prof. Craig and himself, the heart of the animal was unusually large, flaccid, and dilated. He mentioned that as a fact they noted, and to be remembered. He made sections of the lungs and found nothing of any consequence and nothing abnormal.

They examined also the recurrent nerve in different parts of its course; at its origin, in its course in thorax, and in front of the chest, and also quite closely approaching its destination in the larynx. The nerve at its origin and in front of the chest was normal. There was a remarkable change which they did not understand as yet in the portion they examined of its course in the thorax. There was remarkable degeneration and disappearance of nerve fibres from the nerve as it was reaching the larynx. They examined the ganglia and found in the inferior cervical ganglion remarkable changes indeed, when compared with the inferior cervical ganglion taken from a normal animal. These changes were similar to those associated with the action of toxins. They were the same changes as had been recognised in people who died from chronic alcoholism. In some instances the nerve cells disappeared; and there were plenty of examples of degeneration occurring in other nerve cells. The nigroid bodies were disappearing or had disappeared, and the nucleus was displaced. The vagus nerve was normal, but there still remained to be examined the nucleus of origin. Other points he had already referred to were points of importance and interest, and they needed to examine other 'roarers' to see if they could find the same conditions as in the first case.

It was a most remarkable case, and they got it through the courtesy of Colonel Moore. It had been operated on some months ago, the ventricles having been stripped. The animal the next day showed remarkable symptoms of asphyxiation. The officers who had operated came to the conclusion that the only way to save its life was to perform tracheotomy. Changes occurred in the tracheotomy wound. The mucous membrane of the trachea

became thickened, and infiltrated, the lumen was so encroached upon that only a lead pencil could be passed. It was a pronounced roarer. The larynx had also undergone a remarkable change. Some of the cartilages were not only ossified but bulged outwards—convex—on each side, and before the removal of the muscles it looked as if the thyroid gland had moved upwards. He was pleased to note that Colonel Moore, who could not be there that night, had promised to place at their disposal other roarers from the army, and possibly they might report to the Association the result of further investigations as to the changes occurring in the ganglia and other organs.

He would be glad if it would be possible for practitioners, if they had animals that died, if they would obtain for them the ganglia and nerves, labelling exactly the position from which the piece of nerve was taken. It was only in investigating a large number of such cases that one could arrive at a true conclusion as to the pathology of the disease. He thought there were indications that the condition was due to some action of toxin on the nerves—it might be from strangles, influenza, catarrh—but at present they had found something in the ganglion cells. They had yet to demonstrate further. (applause)

PROFESSOR CRAIG said he was indebted to those who had attended the meeting, but he was sorry there were not more present to give their views. It was a most interesting subject. Mr. McKenny and others had referred to the error into which practitioners might fall in examining horses, because a sound might be produced if the head was bent upon the neck, or some alteration made by the reins, and it seemed to him that it was a very important point which was not sufficiently impressed upon young practitioners. It was a point which must always be kept in mind.

Mr. McKenny in his remarks considered that the sound produced in roaring was caused to a great extent by the arytenoid cartilage. But he (Professor Craig) maintained, as he did in his paper, that it was caused chiefly through the vocal cords. His reason for saying this was that the sound was made during inspiration. The left arytenoid cartilage of a roarer did not move in respiration. That might be seen when the larynx was opened for operation purposes. That the sound was abolished by arytenoidectomy was due to the fact that the vocal cord was fixed to the arytenoid cartilage. The thyro-arytenoid ligament, which formed the essential portion of the cord, was thus slackened, and the air could not pass into the ventricle as in ordinary course.

Another question which Mr. McKenny asked, and which he tried to explain, was the cause of the variation in distress observed in the course of the disease. Some horses that were roarers were not much distressed even after severe exercise; although they made loud noises they were able to win races. Other horses were remarkably distressed after only a moderate amount of work or exercise. What was the reason? The principal reason was that the larger proportion of distress was caused by an affection of the heart. It was quite possible, although it was not right to judge from one case, that the degeneration which the Principal had found in the cervical sympathetic ganglia in connection with the case of roaring that he had mentioned might account for the distress which was particularly noticed in some cases; and again by its bearing upon the action of the heart and circulation generally.

As for the production of the disease through an affection of the lungs or stomach, he did not know that any definite evidence was to hand. No doubt the disease was produced by certain foods, as for the example the mutta pea, and in that case one might take it the food materials must have acted after they were absorbed upon certain portions of the nervous system, and so indirectly on the larynx.

He agreed with McKenny that it was an error on the

part of a Veterinary Surgeon who rejected a horse because it had a fine neck. They could not say that if a horse had a fine neck he was a roarer, or was going to be a roarer. It had been the case that some roarers had fine necks, but it was hardly fair to put it down as a law which was to be followed.

Mr. Allen had referred in flattering terms to the paper that he had written, and he thanked him for his encomiums, coming as they did from such an able and experienced veterinary surgeon.

Mr. McKenny referred to the fact that horses which sometimes became roarers were handled so much upon the left side, and suggested that that might have some effect upon the production of the disease. It was difficult to give an opinion upon that point. The investigation that was made in the case of the particular horse to which the Principal referred suggested toxic action rather than defective handling in the production of the disease.

He noticed in that case a peculiar point. The opening in the trachea was only sufficiently large to admit a lead pencil, yet the horse was able to trot and canter. It was remarkable that such a small passage would permit of such severe exercise on the part of the horse.

Another curious thing was that the horse was chloroformed to death, and died quickly, really from asphyxiation. In casting horses for diseases or conditions which did not conform to the definition of roaring, it might perhaps be better to consider that they suffered from some respiratory disturbance or defective respiration. If a horse was put down as a roarer or a whistler it was nearly always regarded as such for ever afterwards.

Mr. Howard also referred to the action of such agents as strangles and diseases of the larynx, and said they were not of themselves the exciting cause, and with that he agreed. Horses might be 'roarers' or 'whistlers' which had never been affected with strangles or other diseases. The point of interest here was that horses that were 'roarers' and 'whistlers' had been taken to certain climates, and the progeny of these horses had remained sound. If the same horses had remained in this country, and been kept for stud purposes, the progeny probably would have become unsound from the same condition.

Mr. HOWARD: Had these diseases existed in those other countries?

Prof. CRAIG: Oh, yes! The answer was that the other climates were dry, and the animals were not affected to the same extent.

He was interested in the cases referred to as complete paralysis of the nostril, and the spasm of the larynx. He thought that in future practitioners would assist them in trying to investigate further this important condition if they sent any cases found at post-mortems. They should be sent in fresh condition, so that they could make something of them (Applause).

VOTES OF THANKS.

Mr. WILKINSON proposed a vote of thanks to Prof. Craig for his excellent paper, which they had had an opportunity of so fully discussing.

Mr. HOWARD said that it was almost unnecessary to second it. Every member was not alone thankful to Prof. Craig, but they actually felt proud of the paper. He thought that the paper would be a landmark in the future history of the question of roaring and whistling with the veterinary profession. He was sure Prof. Craig must have had a lot of trouble in preparing it, and he hoped that some day they would wake up and find that he had discovered where they were about roaring. (Applause).

The motion was passed with acclamation.

Prof. CRAIG said it was a pleasure to write the paper, and he read it in the hope of getting information. He prepared it in order that they might have some definite

views put forward on the subject, and to hear the views of Irish veterinary surgeons on the matter. He knew they paid particular attention to the diseases of respiratory organs in examination of horses for soundness. He thought therefore that was the best place at which such conditions should be discussed (Applause).

Mr. DUNLOP proposed a vote of thanks to the Chairman for his conduct in the chair. He was pleased to hear his remarks about toxin and the recurrent nerve leading to the larynx. He mentioned a case which came into his yard of a valuable horse which contracted influenza and rather suddenly became unsound of its wind. It was a confirmed roarer and was never cured. This may have been an instance of the influenza toxin acting on a pre-disposed nerve and thus causing paralysis. The Chairman's remarks had been most instructive (Applause).

The motion was passed with acclamation.

The PRESIDENT briefly acknowledged the compliment, remarking that it was always a pleasure to come there, as he always learnt something.

LANCASHIRE

VETERINARY MEDICAL ASSOCIATION.

The quarterly meeting was held at the Grand Hotel, Manchester, on December 7th. the President, J. W. Brittlebank, Esq., Manchester, in chair. The attendance included Messrs. Woods, McKinna, Clarkson, Sumner, Wolstenholme, Burndred, Share-Jones, Holroyd, Wright, Whitehead, Lloyd, Giblin, Edwards, Price, Walker, Mattinson, Prestner, Stent, Munro, Holburn, Ackroyd, Ingram, Wilson, Ellis, and G. H. Locke. Visitors: Messrs. Hornby, Spreull, and Turner.

Apologies for absence were received from Messrs. Annett, Carter, Abson, Taylor, Faulkner, Packman, Hobday, Pillers, Lawson, and R. Hughes. It was explained that Mr. Taylor was absent on account of illness, but that he was much better, and thanked all friends for their kind enquiries.

Mr. SHARE-JONES proposed, and Mr. Holburn seconded, that the minutes of the last meeting be taken as read. This was adopted.

Nominations. Messrs. W. H. BRIDGE, Bolton; E. R. EDWARDS, Board of Agriculture, Manchester; A. RICHARDSON, Liverpool; J. Spreull, and H. A. TURNER, Manchester, were nominated for membership by Mr. Locke.

The SECRETARY (Mr. Locke) reported having written to Mr. Worthington, Wigan, asking him to reconsider his proposed resignation, but no reply had, as yet, been received.

Letters of acknowledgment from the families of the late Prof. Williams and Mr. H. D. Chorlton were submitted.

A letter from the Editor of *The Veterinary News* was again submitted in reference to their fund for assisting a member of the profession in the appeal raised by the London County Council to compel veterinary surgeons to pay for the use of the College crest. When previously submitted the letter was referred to the Council of the Association for consideration. Mr. Locke reported that the Council had no recommendation to make on the subject.

Mr. LLOYD proposed that a subscription of £2 2s. be made. Mr. Holburn seconded, and the proposal was carried.

ELECTION OF OFFICERS.

President. Mr. Wolstenholme expressed pleasure in proposing that Mr. BRITTLEBANK be asked to retain the presidency for the coming year. There were many reasons why he thought they should do this, primarily because of

the excellent manner in which he had carried out the duties in the past year, and also because in the coming year, when the Association celebrates its jubilee, more work would be thrown upon the officers than usual, and it was therefore desirable that they should have a President who is used to the office. Mr. Woods seconded the proposal which was carried.

Mr. BRITTLEBANK returned thanks for the renewal of their confidence, and expressed his intention of doing everything possible to further the interests of the Society.

Vice-Presidents. The Council recommended that the following gentlemen be elected: Messrs. Taylor, Faulkner, and Wolstenholme. Mr. Locke proposed this, Mr. Lloyd seconded. Carried.

Hon. Treasurer. Mr. Woods stated that the retiring Hon. Treasurer, Mr. Packman, had, at a recent Council meeting, expressed a strong desire to relinquish this position, his reason was that these meetings clashed with the meetings of his Masonic Lodge. It was very necessary that the Treasurer should be present, and whilst they would be sorry to lose Mr. Packman's services in this respect, they ought to meet his wishes and accept the resignation. That being so he proposed that Mr. Stent be appointed Hon. Treasurer. Mr. Locke seconded. Carried.

It was decided that a letter be sent to Mr. Packman thanking him for his past services and stating that his resignation had been accepted with regret.

Hon. Secretary. The President said he wished to have the honour of proposing that Mr. Locke be re-elected Hon. Secretary. They had an onerous year in front of them and could not do better than stick to the man they knew.

Mr. SUMNER had great pleasure in seconding this. Mr. Locke, he said, was the most desirable man for the post, and they could not possibly think of another. Carried.

Mr. LOCKE, in thanking the members, reminded them that he was now entering on his fourteenth year of office. His desire had been to continue until their jubilee, and, as this occurred next year, he dropped the hint that it was his desire to relinquish the position at the end of the ensuing year.

Hon. Auditors. Messrs. Faulkner and Taylor were re-elected. Proposed by Mr. McKinna, seconded by Mr. Wolstenholme.

Council. Mr. Locke said it was proposed to make a slight change this year in the Council, for the reason that the three Vice presidents were already members of the Council. That left room for three other persons, and it was proposed to add the names of Messrs. McKinna, Clarkson, and Munro. This was adopted.

OTHER BUSINESS.

Mr. LOCKE reported that the Council had duly considered the suggestion that the date of the April meeting be altered, owing to that date clashing with the Council meeting of the Royal College of Veterinary Surgeons, and they recommend the Association to hold their first quarterly meeting on the third Thursday in March instead of the first Thursday in April.

Mr. LLOYD gave notice of motion that the recommended alteration be carried into effect.

Annual Dinner. It was decided to have an annual dinner as usual. A suggestion that ladies be invited did not meet with support.

Entertainment Fund. Mr. LOCKE wished to thank those who had so generously responded to the circular on this matter, and said the committee would be glad to hear from those who had not yet responded.

RETENTION OF THE PLACENTAL MEMBRANES.

By Mr. W. ACKROYD, M.R.C.V.S.

This condition is one of interest and importance, owing to the commonness of its occurrence and to the loss it causes to cattle owners, especially in dairying districts. It is not associated with a large number of fatalities, but the loss in condition, loss of milk, and various chronic conditions resulting make it of sufficient consequence to those concerned. It also has some significance from a public health point of view.

The condition needs no description at this point as it is not a question of difficulty in recognition, excepting a few cases of dispute where improper steps may have been taken for concealing the fact in cows offered for sale.

I find it very unsatisfactory to take a review of the alleged causes of this retention. Those most commonly quoted are abortion, chills, exhaustion from travelling, etc., previous to parturition, prolonged parturition, difficult parturition, precipitate interference with parturition, and any debilitating condition.

In addition to those above stated, I find that laymen believe that a cow having retained the membranes once is more likely to do so at the next calving, also that many allege that one case is often followed by others, this suggesting that it may be a disease *per se*, and be due to some special infection.

Finally it may be stated that in some cases, the membranes may be retained after separation of the cotyledons, either from inertia of the uterus, contraction of the os uteri, or very rarely some other mechanical condition.

But the very varied conditions thus frequently alleged may not be present at all, and in many cases the retention takes place in animals carefully treated and apparently otherwise in a normal condition.

To arrive at a useful conclusion in this matter it will be well to look more closely at the essential condition of retention; that being surely, that the union between the fetal and maternal cotyledons is retained, instead of the disengagement which usually takes place at birth or very shortly afterwards.

The branched villi of the cotyledons of the cow would seem to offer more likelihood of retention than the simple villi on the chorion of the mare.

Physiologists, so far as I have been able to find, offer little information as to what takes place immediately following birth, it being stated that expulsion of the membranes follows, and results from contraction of the uterus.

But the uterus may be contracted without the membrane being expelled, and one would like to hear what is known of the more intimate changes which take place between the maternal and fetal cotyledons in normal cases. One finds very varying degrees of intimacy between the cotyledons when removing the membranes, and whatever is the cause of this must surely be in relation to the actual reason for retention; and the many varied conditions named previously may be dismissed, at any rate as actual causes.

Condition of Animals Retaining the Membranes.—As stated above, there is not a large proportion of fatalities, the results commonly found being:

1. Loss of condition. Animals which continue to feed well will lose condition, whilst those with marked fever lose flesh very rapidly.
2. Loss of milk. Sometimes to the extent of lessening usefulness through the milking period.
3. Various sequelae, such as septicæmia, pyæmia, metritis, in some cases metro-peritonitis, and in others an endo-metritis.

4. Debility, as from diarrhoea, or following the high temperature, and loss of appetite.

5. Leucorrhœa. This follows almost invariably if the membranes be not removed.

6. Possible danger to health of persons using milk.

Symptoms.—These vary with the length of time the membranes have been retained since calving. In most cases some portions of the membrane are hanging from the vulva, though in others none may be visible, but a discharge of varying offensiveness is noted.

Very early the temperature rises and may be 101.5-6, pulse is more frequent but varying in character. Appetite flagging, and in bad cases suspended. The tail is switched about, and in advanced cases, or where there is vaginal irritation, the back may be arched; with suppressed moan in severe cases with uterine complications. The condition found in the vagina and uterus may be noted when dealing with removal of the membranes.

Treatment.—Formerly much faith seems to have been placed in various cleansing drenches, but these do not find much favour nowadays. I have never noticed any drug to have any effect in expelling the membranes. Ergot, mugwort, savin, laurel berries, mag. sulph. have been used in the manufacture of cleansing drenches, and some have been much praised. Some practitioners give various tonic and febrifuge medicines whilst waiting for the membranes to come away, or till they yield to simple traction on the hanging portions.

But the treatment most commonly practised to-day is manual removal of the membranes, with medicinal treatment to follow, as symptoms may seem to warrant. A good deal of discussion has taken place as to the most suitable time for this removal, but it might surely be suggested that the choice of time should be dependent on two things:

1. The earliest period at which removal can thoroughly and safely be made; and
2. That, if possible, removal should take place before there has been time for any septic mischief.

Some advocate the removal so soon as it is apparent they are being abnormally retained, and thus favour removal in the first 24 hours. Others do not believe in separation of the cotyledons, but wait six or seven or more days until decomposition may enable the membranes to be simply drawn out.

Personally, I have found it impossible in the majority of cases to remove the membranes perfectly within the first 24 or 36 hours; the extent of the uterus at that period, and the intimacy of the attachment of the cotyledons offer obstacles to the operator. For some time I have removed them about the third day, and find that the uterus is more easily reached to its full extent and the fetal cotyledons are more easily separated than at an earlier period. Nevertheless, if removal at the earlier period, say 24 to 36 hours, could be always properly effected, it would be preferable to waiting even three days.

When removing the membranes care should be taken not to add to the infection already present in the uterus, and to this end a good supply of clean hot water and antiseptic preparations should be at hand. Of antiseptics I prefer the various emulsifying tar preparations, as the mixture is lubricant to some extent. Some find it necessary to very carefully put various antiseptic preparations on the arms before starting, as infection of the operator sometimes takes place. Personally, I thoroughly soap the arm, as it is thus very easily cleaned (as it has frequently to be in all cases), and I have had no personal trouble from infection.

The tail and vulva should be carefully cleansed, and the vagina too should be examined, as in some cases of vaginitis it may be advisable not to insert the hand. When the os uteri is reached, it may occasionally be found, even in two or three days, to be tightly and closely contracted, and may need to be dilated with the fingers

before the hand can be passed into the uterus. In some cases the membranes may be held by the contraction of the cervix after detachment of the cotyledons has taken place, and in these cases removal is accomplished at once. When passing the hand into the vagina and uterus the mass of membranes should be gathered up with the other hand, so that assistance may thus be given.

Very varying conditions are found in the uterus. In some cases the membranes are much shrunk in bulk, occasionally they are cedematous, whilst sometimes, even in two or three days, they are broken up and can only be removed in pieces along with the fluid portions. The fluid found varies very much too, being either thick and even the consistence of gruel, or thin and often abundant and very fetid. To the operator the main point of interest is the number of cotyledons still attached and the nature of their attachment. Occasionally one finds only a few cotyledons need to be released, and the mass is then free, but in the great majority of cases the cotyledons all remain attached. The intimacy of this attachment varies too, sometimes attachment is easily and quickly accomplished, whilst, again, great care and patience are needed, and even with that every portion may not be removed. Another difficulty often met with is in reaching the extreme end of the uterine horn and in separately dealing with the cotyledons there. One often finds that in some cases the maternal cotyledons come away, but it will be found that necrosis has taken place, sometimes in a considerable number of them.

Owing to some of the above difficulties, it will be found that in some cases portions of the membranes cannot well be removed. Following this removal comes the question of the immediate treatment of the uterus. In my own practice the uterus is swabbed out with a soft clean cloth soaked in some antiseptic, and if a large amount of fluid is present it may be scooped out with the hand. Formerly I used to irrigate the uterus with antiseptic fluid, but I have long ago dropped it, finding it difficult to remove all the fluid, and the portion retained quickly became septic and caused increased mischief. On the other hand, swabbing out as described above induces contraction of the uterus and expulsion of contents.

Uterine suppositories may be used, but I have not used them sufficiently to have any very decided opinion as to their value in these cases, though I have found them useful in certain cases of vaginitis.

Medicinal Treatment. This should be guided by special conditions presented. Salicylate of soda, quinine, hyposulphite of soda, nux vomica, with various tonics may be given as thought necessary.

Use of Milk. This matter can only be dealt with satisfactorily by capable examination of the milk, and experiments as to the effects of its use. It seems to be a question for the bacteriologist. If local authorities prevent the use of the milk it seems reasonable to expect some compensation, and I should like to hear from you if any such action is taken.

Legal Aspect. I think the law is clear as to the liability of a seller for a cow not properly cleansed, but in one or two cases I have seen unexpected difficulty as to proof of the conditions, and of course very varying evidence as to inferences to be drawn.

Finally, I should like to put some questions to you as a review.

1. What is the cause of the cotyledons not disengaging?
2. Any other method than those mentioned to remove them?
3. What is the nature of the varying infection which takes place?
4. Is there any special infection which can cause this condition?

5. What is the effect on the milk, and what is to be done with regard to it?

DISCUSSION.

The PRESIDENT remarked that they had listened to an instructive paper on a very interesting subject. He hoped to hear a good discussion.

Mr. WOLSTENHOLME asked what objection there was to removing the placental membrane at the time of calving, other than the physical difficulty?

Mr. ACKROYD replied there was none.

Mr. PRICE thought the subject had been very well traversed. He used to irrigate, but found there was a lot of straining. He found it impossible, in a great number of cases, to remove the membranes immediately, but thought from the third to the fourth day was about the best time. He found in a number of cases that it is quite the habit of Irishmen when they come to the fairs with fresh calved cows to cut off the "cleansings."

Mr. LLOYD thought a difficult question had been put to them as regards the causes of retention. Mention had been made of the effect of chills, and from his experience this had much to do with it. It had been his lot to watch carefully, and to take the placenta from cattle that had calved normally, as well as from difficult cases, and he found if the cow had retained the membranes she was either opposite an air inlet, window or door. The best means to get a cow to part with the membranes after calving was, in his opinion, to cover her up and get her to lie down. Comparisons had been made between the mare and the cow and sheep, but the anatomical condition of the cotyledons was different. As regards the use of the milk, he thought this undesirable. He was certain that milk had a tendency to take up bad smells, and at such times was liable to contamination. Of course it was probably not milk at this stage but "beastings." In respect to the milk supply, he had no doubt that the President would bear him out when he stated that 10% of mixed milks taken for the purpose of testing by the inoculation test for tuberculosis caused death in the inoculated animals within a very short period. Possibly a percentage of these might be due to sepsis introduced during retention of the membranes.

In reference to the cutting off of the placenta, it was usual in Scotland to sell a newly calved cow as being "correct."

Mr. MATTINSON asked whether it was some bacterial infection that caused the retention of these membranes? Mention had been made of cows dying from exhaustion, but he thought it would be probably more correct to say that toxæmia has caused death. As to "hurried breathing" being a symptom, he would go further, and say grave lung trouble is present. For removal of membranes he thought moderate traction to be useful. He never used irrigation unless compelled by the owner.

Mr. MUNRO said he frequently practised irrigation, but always took care to remove all the fluid from the womb, and for this purpose he used a sponge. He had not had bad results. He usually left the removal of the membranes until the fourth day.

Mr. SUMNER thought one of the points arising out of the subject was whether retention of the fetal membranes can be infective—can it cause other cows to hold their membranes? He would hesitate to say that such a condition might arise, but they would all agree as to the desirability of treating these cases as if they were injurious to other animals, particularly if they are in process of lactation. They knew that where they got one retained cleansing in a herd they would get more. As to traction, he had been taught and practised the removal of the cleansing by winding it round his arm with the object in so doing of getting some traction and

reaching the furthestmost portion. For some time he had ceased irrigation.

Mr. MCKINNA regretted to differ from the general tone of the discussion, but he felt bound to say that in his practice irrigation had been successful, and he had seen no untoward results. He commonly found that he might have to irrigate on three successive days, but of course he took care to remove as much of the fluid as possible.

Mr. WOLSTENHOLME looked upon irrigation of the womb after parturition as being a case of blindly following the medical profession, but the conditions are absolutely different. It is one of the best things possible in the human patient, but in the case of the mare or cow it is not well. He thought it hardly correct, when speaking of the lower animals, to use the term placenta or placental membranes.

It occurred to him that a great deal of the trouble experienced with the cow in calving as compared with the mare and sheep and other animals was due to what he would call unfair treatment of the cow. Often it was merely turned into a milking machine; it got insufficient exercise, its food was given more with the idea of producing milk than maintaining life, and altogether the surroundings of the cow are such as predispose to trouble during parturition and subsequent period of lactation.

No one had mentioned cases of post-partum hæmorrhage. He failed to see why the membranes should not be immediately removed after parturition. In the human subject it was considered bad practice to leave any portion of the membranes. With respect to chills he said they could get these from within as well as from without. It appeared strange to him that an animal coming to the parturition act under the conditions to which she was quite accustomed as regards ventilators, etc., should have retention of membranes attributed to these causes.

The PRESIDENT wished to add his mead of praise for the excellent paper. Those of them in public offices were not expected to know anything about practical matters. They were there to look on and admire their brothers in private practice, and of course hesitated to venture any opinions on their sacred precincts. They had, however, some experience of private practice in country districts, and remembered some of the things they used to come in contact with very much oftener than they wished. He confessed to being in the dark as to the cause of the retention of placental membranes. He thought that difficult parturition and consequent atony of the organ had much to do with it. With regard to necrosis, he had seen this frequently, but had looked upon it as having nothing at all to do with the actual removal of fetal membranes. He thought that a possible explanation was that partial necrosis commenced before the actual parturition.

As inspecting officers they came into contact with imported cattle in regard to which it was difficult to say whether they were suffering from tuberculosis, or other conditions characterised by wasting, or due possibly to some transient cause. Mr. Lloyd had referred to the fact of 10 per cent. of animals inoculated with the sediment of mixed milk having died rapidly from septic infection. This was not the history in Manchester now, and had not been for many years. He could hardly agree with Mr. Lloyd when he attributed septic infection introduced from retention of the fetal membranes as one of the main causes. As a matter of fact in the early history of the supervision of the milk supply in Manchester, many of these so-called infections had been followed up, and in a fair percentage of cases Professor Delépine was able to come to the conclusion that dirty conditions, polluted water supplies, and purulent conditions of the udder were the main causes.

He was glad to note that Leeds had decided to pay

compensation to farmers in view of their excluding from the milking herd cows with retained fetal membranes. Leeds was always progressive; they had not thought fit to pay such compensation in Manchester. It was easy to talk about compensation, but possibly the better plan to pursue would be to compel isolation, and at the time when farm buildings were erected to see that sufficient accommodation for this purpose was provided. At present, of course, provision for isolating animals was, on most farms, entirely inadequate. He would like to say that they had no power to prohibit the use of milk from such cows, but he was quite certain that if such milk was sold it could be only in very small quantities.

A cordial vote of thanks was passed to Mr. Ackroyd for his paper, proposed by Mr. Lloyd, seconded by Mr. Burndred.

Mr. McKINNA proposed, and Mr. Burndred seconded, a vote of thanks to the retiring officers.

The PRESIDENT, in reply to this vote, said that the best thanks their officers could have was to see such a large number of members attending as were present that day, and he hoped that it was merely an indication of an increase of interest in the business of the Association.

WEST OF SCOTLAND VETERINARY MEDICAL ASSOCIATION.

A meeting was held on the 21st October, within the Religious Institution Rooms, Buchanan Street, Glasgow. The attendance was a very good one, the following members and friends being present: Principal McCall, Principal Bradley, Profs. Gofton, John McCall, Messrs. Macfarlane, Begg, Roy, Weir, Reynard, Brown, Robertson, Douglas, McIntyre, Forbes, McMurich, McDougall, Scott, Mitchell, and final year students.

Mr. James Macfarlane, the President, occupied the chair, and when the minutes of last meeting were read and approved, Mr. Roy asked the whole meeting to join with him in asking that the Secretary insert a note in the minutes to perpetuate the memory of the late Robert Miller, of Strathaven, our esteemed friend and fellow member, who died since our last meeting here; and also send a letter of condolence to Mr. Miller's widow, to all of which the members were at one with Mr. Roy.

The PRESIDENT then asked Mr. Gofton to explain further the position of the "proposed reconstitution of the National Veterinary Association and Union of the Societies, as this meeting was now about to discuss the advisability of promising to become affiliated to the new Association.

Mr. GOFTON said this scheme had now been before the Societies for a number of years, and the National had had it under consideration for two years, and they had now agreed to the amended rules with very few alterations indeed, and they would be adopted by them at the March meeting of next year (1912). They were now in a position to ask this and other Societies their position with regard to the amalgamation—whether they intended to join or not.

The PRESIDENT said that as this was one of the best meetings they had had for some time he considered it should be put to the meeting, whether for or against: in his own opinion it was a very wise thing to have a strong Society; it was specially good when any Parliamentary matter was brought up, as instanced by the Insurance Bill and the Medical Association at the present moment. He then moved that we go on with the reconstitution scheme, and moved that "we as a Society should affiliate to the National as reconstituted."

Mr. BEGG seconded, and said it was certainly our clear duty to join this Society, and on the motion being put it was carried unanimously.

Mr. ROY pointed out that they would certainly have to score off a great number of old non-paying members and for a meeting or two it had been so poorly attended it was sometimes difficult to get a quorum.

The SECRETARY then read a letter from *The Veterinary News* regarding the case now pending London County Council *v.* Kirk in which the use of the veterinary crest on stationery was claimed as being taxable; and asking our support.

The meeting considered it would not be a good plan to fight over the matter with the County Councils, as it would only give more publicity and tend to further actions being taken.

Mr. BEGG proposed that £1 1s. be sent; it was evident from the communication that some expenses had already been incurred, and it was the County Council who were forcing the matter and not Mr. Kirk. Mr. WEIR seconded, and the motion was carried.

The chair was then taken by Mr. Hugh Begg, an ex-president.

HORSES SUITABLE FOR HEAVY CITY WORK

MR. JAMES MACFARLANE, M.R.C.V.S.

Gentlemen.—I am not going to inflict on you anything so painful as an old-fashioned Presidential address from me would be. It was not my intention to address you to-day at all, because I was hopeful of getting some specialist in a particular branch of our profession to give a lecture, or demonstration on his own subject. But a fortnight ago our respected friend and Secretary, Mr. Mitchell, informed me that I would have to deliver my presidential address. On thinking it over I came to the conclusion that the best way of fostering interest would be to deliver a few remarks on such a subject as the one I have chosen, with the intention and hope of inaugurating an effective discussion.

The title "Horses suitable for heavy town work" involves a big field, and much can be said, but in a lecture such as this, I know I will be pardoned though I only deal with it superficially. I claim for my subject that science has done very little to enlighten us, and that where we can get really reliable information is from men who have made it their life's study, and have stored up their experience. When we leave College, proud of the magic letters we are entitled to use, we have very decided views on the "soundness" or "unsoundness" of the horse, but I venture to think we all of us have considerably changed in our views since that time. At the outset, I wish to remind you that what I have to say relates to heavy or slow work horses.

The Clydesdale is in many respects the ideal horse for heavy town work; but are not the present showyard fashions playing havoc with their size and strength of bone? Is not a "good" big horse always a third more valuable than a "good" medium-sized one? How are our breeders to regain and maintain size? Can it be done by breeding only from big dams and sires, or do certain strains of the Clydesdale, independent of the size of dam and sire, invariably produce big geldings? Many present-day fashionable Clydesdales are too pampered to produce hardy town animals, and there is not enough attention paid to the food of young stock so as to help their growth.

Would serving our biggest mares with a comparatively clean boned, scant of hair, Shire stallion be a benefit? or would better results accrue from importing big sized, bouncy, clean legged Shire mares, and crossing them with a Clydesdale sire specially good of his legs and at the ground? Would the resultant crosses, if bred from,

still give us a blend, or would they throw back to either the Shire or the Clydesdale?

My experience of pure-bred Shire horses in our hilly towns of Scotland has not been satisfactory, and I know that in Newcastle-on-Tyne, where there are very steep streets, the Clydesdale compares more than favourably with the Shire. Shires go up quickly on their hind fetlocks; as a class they are too slow in their work to suit Scotch contractors, and in addition they are more subject to grease and weeds than the Clydesdale. If you do get a good, big-sized Shire, seasoned to his work, owing to his great bulk he is the ideal for shifting heavy weights such as boilers and castings.

There is still another distinct class of horse in considerable demand, namely, the heavy gyp horse; clean, sharp, and hard of his bones, devoid of long hair on his legs, and of prepossessing appearance, suitable for merchants' lorries, where he has to draw a fair load and cover a great amount of ground during his daily rounds. The heavy American gyp, that was freely imported into this country until about nine years ago, was the ideal for this class of work, and had our contractors here treated them better—by giving them easy work until they were acclimatised—there would have been more of them on our streets to-day. I know many of them that have withstood the strain and stress of 8-15 years of hard town work and are as fresh on their legs to-day as when they were bought.

Their points, *par excellence*, were, they had big, sound solid feet, their bones are like flint, they had a long, free, springy step, were remarkably round with well sprung deep ribs, they were easily kept and always locked well, and were genuine workers.

Clean boned Clydesdales, Irish-bred gyps, home cross-bred gyps, and a few pure-bred Suffolks are at present doing this class of work, but I am convinced none of them are as satisfactory or wear as well.

I often wonder if a similar breed could be established in this country by importing breeding animals of the Percheron type, either from France or America. Again, it has occurred to me, would not Suffolks improve if bred in our hardy more severe climate? I am convinced a breed of gyps would pay the farmer, because they would be of a type and size to suit his work, and when ready for town work would meet with an eager demand, at prices varying from £55 to £80.

Apart from the soundness, breed, and quality of an animal, he must be a genuine true worker, or his value to the contractor is *nil*: the horse that, to use a popular phrase, "will draw at a growing tree," is invaluable—provided he is given a capable careful driver; but it is usual that the willing beast gets the work to go, and thus many a good sound animal of this class becomes decrepit before his time.

Temperament, and the manner in which a horse is broken to work, play an important part in determining his future usefulness. Temperaments may be divided into three classes: 1st, phlegmatic, slow and easy going; 2nd, nervous—active; 3rd, medium, which is a blend of the other two.

The phlegmatic horse is good for slow work and is easily kept. The nervous horse may do well on regular routine work with a calm, even-tempered driver, but he cannot stand changes of driver or work. The medium-tempered animal is the one which pays its way best, having a certain amount of temper and being a dour worker.

Before considering my next point I wish to draw your attention to a deplorable practice that is spreading among our present day farmers, namely, the buying in of foals, colts, and fillies, instead of breeding them. It is a selfish course, and is to a great extent the cause of there being a shortage in our horse supply; and the economy of it can be questioned when one considers the price young stock is fetching.

Do our farmers give enough attention to the breaking and training of horses that are to be sold into town work? How many farmers own a lorry? Every farmer should pay as much attention to the training of his heavy horses as he would to a light horse intended for harness purposes. They should mouth animals requiring it; use them to handling a lorry, and if near a town accustom them to traffic and to walking on stone-paved streets.

Farmers make a grave error in not sending their horses to the smithy for attention every six weeks. How many horses do we examine with overgrown, broken, or defective feet due to this neglect? Farmers are hard to convince, but I am certain that horses, no matter how perfect and well grown they are, should be kept at farm work until five years old, and they would prove more satisfactory afterwards to the contractor.

Are the present laws relating to soundness satisfactory, including our liability as veterinary surgeons? A sound animal is one that is neither diseased nor suffering from the effects of disease that is likely now, or at a future date, to impair his usefulness. I think it would be far better if our clients would ask our advice as to the suitability of the animal for their work rather than tie us down to say sound or unsound, because many an animal, though sound according to legal definition, is defective in conformation and sure to prove unsatisfactory. Again, there are others unsound but, owing to their age, temperament, and conformation, are otherwise useful animals, likely to wear well.

Before going on to consider scheduled unsoundness, I would like to consider one or two phrases of conformation.

Undoubtedly the foot is the most important factor in determining an animal's usefulness, and the old adage "No foot no horse" should be continuously kept in mind. I do not like too big a foot, as blacksmiths are apt to mutilate them by cutting them down, thus saving iron. The under structures must be covered with solid, thick horn, the wall should be circular and of sufficient depth, the sole should be concave, the frog, quarters and heels open and well defined. In examining feet we should bear in mind how much they can be improved by regular and careful shoeing.

Is flat sole detrimental if well covered with horn and the horse has otherwise good feet?

Big, strong, well defined joints are valuable, even though they do handle a bit rough or uneven, provided the animal is a straight goer and flexes them equally well.

A useful animal should have his shoulders, forearms, thighs, quarters, and loins well and symmetrically covered with muscles.

Horses with sidebone associated with ringbone should invariably be condemned; but is sidebone alone an actual unsoundness, provided the animal is five years old and has good, big, open feet? About 50% of all horses bought sound develop sidebone sooner or later if put to work on our streets.

I have never treated a horse that was lame from sidebone pure and simple. We often get sidebone associated with sprain of the back tendons causing lameness, but as over 70% of the horses we treat for lameness are lame from sprain of the check ligament, or sprain of the flexor tendons, it naturally follows, owing to the prevalence of sidebone, that they are often associated. Again, in most of the severe cases of sprained tendons that I have been called to treat, the animals were clean at their hoofheads.

Horses with either high or low ringbone should be condemned. I do not think ringbone is common in the Clydesdale.

Is not keratoma a frequent cause of lameness in town horses, and how are we to distinguish between it and low ringbone, or even disease of the pyramidal process

I am of opinion side ringbone is not an actual unsoundness if present without being associated with true ringbone or sidebone. Many horses that walk intoed handle rough on the side of their pastern joints.

Splints on a heavy horse seldom impair his usefulness.

A horse with chronic shoulder-slip can with safety be bought for town work if there is no lameness present, and the animal walks with a natural, free step.

Curb is a rare cause of lameness, though I have treated it occasionally.

I seldom have occasion to treat bone-spavin lameness. In examining horses for soundness I prefer horses with rough, broad hocks to those of the smooth fine variety; and I do not object to odd hocks, provided the horse goes sound and flexes both joints equally well.

Many horses that have been made up for sale, therefore not in regular work, handle boggy and soft of the capsules of their hock joints. These horses can be purchased, and if the swellings do not disappear they seldom get worse. But if the swelling is hard and tense, and there is a certain amount of stiffness, then certainly condemn; because true bog spavin causes acute lameness that is most difficult to cure.

Stringhalt is uncommon. I would not pass an animal with excessive stringhalt, or one that shows it slightly every time it is turned, because they always tend to get worse; and besides being unsightly, they are heavy on hind shoes and liable to spring saucer cracks. Many horses show a quickness of their hind action when turned on stone sets for the first time, but I would defy you to make them do it once they get used to the hard slippery pavement.

A "shiverer" I would not buy, although it is remarkable how some of them wear. I know a pronounced shiverer that has been fourteen years in town work, and he still lies regularly and can back his lorry when required, and is a very true puller. I would like to know an infallible method of detecting "shivering" in the early stages.

Apart from shivering, many animals seem to suffer either from injury to the muscles of the back or injury to the spinal column, which makes them unable to back properly, or hold back their loads going down hill; and they are usually footless, but good workers forward. Our text-books give us very little information on this subject. Many horses that seem to work perfectly during their trial develop it after being put to hard work.

I reject all horses that are broken of their wind or roarers, but I pass all animals that grunt to a stick, provided they are otherwise sound of their wind.

We should always auscultate the heart after the animal has been trotted, to find out if the heart beat is normal and regular.

The molar teeth should be examined to see if they are regular and free from caries.

Finally, one should be very guarded in advising the purchase of a horse that has any abnormal swelling of one or more of his legs, for though it be slight, it is usually indicative of a previous attack of lymphangitis.

In conclusion, I may remind you that the perfect horse to-day may be imperfect to-morrow, and it is a blessing to meet with clients that thoroughly realise this.

DISCUSSION.

Principal McCALL said it was a most interesting paper, and on most points he was at one with Mr. Macfarlane, and there were many ideas in it that could be with advantage discussed, but he would confine himself to one point—the getting of size and quality. He had fifty years experience on the breeding of draught horses, and he certainly could not recommend the breeding with a Clydesdale mare and a Shire stallion, in fact the produce was invariably "weedy" and unsatisfactory

animals, but the result in breeding with a Shire mare and a Clydesdale stallion were often very satisfactory, and then a big useful animal, with some activity about him, in fact it was on those lines that Lawrence Drew brought up the Clydesdale to such perfection. But it is necessary to keep importing Shire mares, as the crosses are apt to throw back and breed poor stock.

Principal Bradley and Professor Giffon, before leaving to catch a train, eulogised the paper, but would like to have taken up some points with Mr. Macfarlane on the Shire horse, and also some points about lameness.

Mr. REYNARD said he had had the very opposite experience to Principal McCall in the breeding with a Shire mare and a Clydesdale stallion, but good results *vice versa*. He went on to speak on other parts of the paper, on shivering and the difficulty of diagnosing. With stringhalt he would condemn every case. He liked good strong hocks, but not odd hocks. He also spoke of contraction of the feet, and was in the opinion that the blacksmith was to blame for most of this in cutting down and out the heels. He also spoke of the difficulty of being able to get a sound horse, and to the fact of having seldom seen one thoroughly sound.

Mr. G. WEIR said he could not go the length of the last speaker, as he had many times seen a horse one could fault for nothing. He certainly took no notice of splints in a Clydesdale horse if over 5 years old. In the case of sidebones, he would not pass them if pronounced, especially if under five years old, but if over that age he might advise his client to purchase him at a price. Mr. Weir did not think that the country, or any other smith, was to blame for contraction of the foot; in fact no vet. could advise some country blacksmiths how better to spread them. Concussion was the cause of contraction; not paring down of the heels as stated by Mr. Reynard. He would have nothing to do with a shiverer, and only regretted that there was not some means of making a certain diagnosis of this and stringhalt in the latent stages. Ringbone he would pass on no account; he might pass a slight prominence if not around the joint. Of course there were other bad defects or vices in horses that had to be looked for, for instance, crib-biting and wind sucking.

Mr. McMURRICH thought it a very able paper indeed, and was at one with the President on the gyp type of horse for a long and hard day's work. The Irish gyp was one of the very best types we had in the market at present, and in his opinion was far superior to the Clydesdale. He said great stress was often put on soundness, but often a sound horse was a "useless brute" as far as work was concerned, and one of the soundest horses ever he had was also a useless "slug." In cases of stringhalt if the animal is thoroughly seasoned to hard work and not too badly affected he would be inclined to purchase him. If sidebone and no ringbone and the foot was a good, open one, he would be inclined to pass him—with the client's knowledge.

Mr. ROY considered the blacksmith was the friend of the farmer, and was in no way to blame for contraction of the horses' feet as suggested by Mr. Reynard. Mr. Roy attributed the scarcity of horses to the Colonial demand, young stock being sold as high as £150 for ordinary 2 year old fillies. He coincided with Mr. Macfarlane about side-bone, but if Glasgow streets were to be taken as a criterion the number of horses with sawn feet and ornamental firing—there were certainly men who had great expectations of reduction and cure of lameness from sidebone.

At this point, owing to the late hour, further discussion was stopped, and it was proposed to have the essayist's reply at the next meeting. Mr. Macfarlane, however, pointed out that it was better to have something new at each meeting.

Mr. MACFARLANE was pleased with the discussion, but owing to the shortness of time a lot of points were not taken up. He was pleased to learn he was not alone in most of his opinions. As regards the breeding for size, his opinion and experience coincides with that of Principal McCall. Regarding the contraction of feet he agreed with Mr. Weir, that concussion has something to do with it, although there were other factors at work. Mr. Reynard must have misunderstood the remarks regarding the country blacksmith: it was not the capability he was questioning, but it was the farmer that was at fault in not giving them the opportunity to look after the feet regularly. He was specially pleased with Mr. McMurrich's remarks, as they showed the opinion of a man who both treated and owned horses doing contracting work.

The SECRETARY then moved a vote of thanks to Mr. Begg for his conduct in the chair during the discussion, which was carried.

This brought a very interesting meeting to a close.

ROBERT MITCHELL, JUNR., Hon. Sec. & Treas.

FORMATION OF A VETERINARY ASSOCIATION IN KENT.

A well attended and representative meeting of Fellows and Members of the R.C.V.S. practising in the County of Kent was held at the County Hotel, Canterbury, on Wednesday, Jan. 3rd, under the presidency of Mr. Theo. C. Toope, M.R.C.V.S., of Dover, who was the instigator of the movement.

The CHAIRMAN, in the course of a brief address, said he had no need of apology for bringing them together, the replies to his letters, which numbered about 40, spoke volumes in favour of the scheme he would propose, nearly every one wished the project success, although a large number could not attend that day. He was a comparative stranger amongst them, and heartily thanked those present for their response to his call to arms. Coming into Kent some 11 years since, he had much missed the good offices of a Veterinary Medical Society, none being available nearer than London, and he could assure them that were they to unite, much could be done for the common weal of the profession, much that would be impossible by individual effort. If he wanted an example to force home his argument, let them look to the attitude of the sister profession in their endeavours to get fair play under the Insurance Bill; and there were many matters that needed collective action, not only by themselves as a Society, but by the whole profession. He instanced the treatment the general practitioner received at the hands of the Board of Agriculture, whose lay inspectors treated the members of the profession with scant courtesy and less consideration. Our position as meat inspectors was virtually lost, and unless we awoke from our semi-somnolent state the inspection of dairies and milk supply would follow suit.

Quackery, again, was more rampant than ever, and altogether the outlook was not a particularly bright one for the present-day veterinary surgeon. From a social point of view none could say but good would result from such meetings. He personally thanked Mr. James Crowhurst for his help in the organisation of this meeting, and concluded by proposing:—

"That the Fellows and Members of the R.C.V.S. now assembled resolve themselves into an Association, with power to add to their number, to be called the South Eastern Veterinary Medical Association: That they meet three times annually, alternately in East and West Kent: That the Society shall include a President, Vice-Presidents, Secretary, and Treasurer."

In reply to questions, Mr. Toope said he hoped it would be understood that its scope would not be limited to Kent. He had hopes of the cordial co-operation of the adjoining counties, hence the name he had suggested, but up to the present, as a matter of convenience, he had only sent letters to Kentish veterinary surgeons.

Prof. CAVE, dealing with the scope of the Society, said he thought its meetings should be restricted to the county, otherwise it might grow out of bounds as had done the Midland Counties, which though founded by his father in Nottingham, now rarely visited the county.

Mr. L. DIXON, M.R.C.V.S., also thought there was this danger, but suggested that an explanatory letter of invitation to join us should be given to Sussex members of the profession.

Mr. JAMES CROWHURST heartily greeted the proposal and seconded it. He considered such a Society had long been wanted in the district.

Mr. R. ROBERTS, F.R.C.V.S., and others supported, it was put to the meeting, and unanimously adopted.

ELECTION OF OFFICERS.

Mr. E. L. Dixon proposed Mr. JAMES CROWHURST, F.R.C.V.S., as the first President of the new Society, emphasising his remarks by stating that the name of Crowhurst had been honourably connected with the veterinary profession in this and the adjoining county for considerably over a century.

Prof. Cave, in the same kindly spirit, seconded the proposal, Mr. Roberts supported, and the proposal was enthusiastically carried.

Mr. CROWHURST then took the chair, and in a brief speech thanked them for the honour they had done him.

Vice-Presidents.—The following were then chosen:—Messrs. RICHARD ROBERTS, F.R.C.V.S., proposed by Prof. Cave, seconded by Mr. Huband; WILLIAM CROWHURST, F.R.C.V.S., by Mr. Roberts, seconded by Mr. Hogben; E. LYNE DIXON, M.R.C.V.S., by Mr. Hibbard, seconded by Mr. J. Crowhurst.

Hon. Sec. and Treas.—The President proposed Mr. THEO. C. TOOPE, M.R.C.V.S., Mr. Hibbard seconded, and Mr. R. Roberts, in supporting, said he had known Mr. Toope for a great many years in the North of England, and from what he knew he was certain he would do good work for them.

Mr. Toope was unanimously elected, and in thanking them said he hoped they all would as readily respond to his invitation to meet as they had done that day.

Committee.—Prof. CAVE, Wye; Messrs. EBBETS, Rochester; and HOGBEN, Ash.

On the proposition of Mr. Ebbets it was resolved that the first general meeting should be held at Canterbury the second Wednesday in May, at 2.30 p.m.

This concluded the preliminary business.

Mr. JAMES CROWHURST drew attention to the scale of fees allowed by the Kent County Council, which in many cases were utterly inadequate to the time and trouble expended. Taking as one example, the question of value in the case of glandered animals, the fee allowed by the Council was 7s. 6d. only, irrespective of the number of animals valued. Attendance at markets, cattle sales, etc. 2s. 6d. per hour only was allowed, which he considered insufficient; and the mileage also needed increasing to 1s. per mile one way. He had in the past got a slight improvement in that respect, formerly the allowance was only 6d. per mile, but by representing the matter to the Kent County Council they had agreed to raise it to 9d. He fully believed that were the whole of the Inspectors to meet and suggest an amended scale the County authorities would favourably consider it. He had received some time since a letter from the Clerk of the Peace, Mr. Prosser, who stated therein "If the officers affected who are not satisfied will send a joint representation to the County Coun-

cil pointing out in what particulars the present scale was inadequate, and stating exactly what allowances should be substituted, the question would receive due consideration."

Reverting to the question of valuation of animals, he maintained it was no sinecure, and not unfrequently led to unpleasantness between the V.S. and his clients, the latter frequently having an exaggerated idea of the value of an animal; and although he had repeatedly pointed out that the real value of a glandered animal was absolutely *nil*, it was not at all easy to give satisfaction.

Mr. R. ROBERTS thought the whole scale needed careful consideration by all the Inspectors. They were all now greatly indebted to Mr. Crowhurst for what he had already done for them, individually, at considerable personal trouble and expense. The inspection of markets often occupied six hours of their time, beside considerable out-of-pocket expense, six hours practically represented a professional man's day's work, which, according to scale, represented 15s. on monetary value. The time has passed when V.S. value their services at that price. He questioned if the veterinary surgeon ought to undertake the valuation of animals at any time, and probably by doing so they laid themselves open to action at law for acting as an appraiser or valuer without having first obtained a licence to do so, his duty was to act in conjunction with a valuer, and deal exclusively with the question of soundness. A very different fee would be demanded by a valuer than that allowed the veterinary surgeon.

Professor CAVE fully agreed with Mr. Crowhurst and Mr. Roberts on the need for revision of fees, and acting as he did as veterinary adviser to the Kent County Council he would give his hearty support to any suggestions coming from the inspectors collectively. So far he has only once been asked to advise on the question of fees, and on that occasion a satisfactory amendment was made. He agreed that the valuation of animals was not the veterinary surgeon's duty, he should act in these cases in his professional capacity, as a referee.

Mr. TOOPE stated that the question of fees had some years ago agitated the Inspectors of the West Riding of

Yorkshire, and by calling a meeting of them he was to some extent instrumental in gaining an all-round increase in the scale of fees, but not before a somewhat drastic method was adopted.

Mr. GILLARD was of opinion that in no case ought the fee to be less than 10s. 6d. whether we acted for County Council or Town Council, and that 1s. per mile should also be applied for.

After some further discussion, in which all present took part,

Mr. HIBBARD proposed "That seeing the question is of general importance we place on record our views on the inadequacy of the fees, in order to strengthen the hands of the veterinary inspectors who were not now present, in their attempts to get the scale of fees amended." This was seconded by Mr. Gillard, and unanimously adopted.

After a further general discussion it was resolved, on the motion of Mr. Dixon, "That the whole of the Veterinary Inspectors be invited to attend the next general meeting to confer in formulating a revised scale of fees more commensurate to the services rendered."

Mr. W.M. CROWHURST exhibited an interesting specimen of a fractured pubis from a mare who died some time after foaling, from another cause, a long time after the lesion had healed.

This concluded the business of the meeting. Subsequently the inaugural dinner was held in the Hotel, an exceedingly pleasant reunion, two or three of the members meeting for the first time since student days, some thirty years since. The usual loyal toasts having been honoured, that of "The President," proposed by Mr. E. L. Dixon, was most enthusiastically received.

THOS. C. TOOPE, *Hon. Sec.*

Foot-and-Mouth Disease.

The Board of Agriculture and Fisheries have made Orders withdrawing all the restrictions which were imposed by them on the movement of animals in connection with the recent outbreak of foot-and-mouth disease on premises at Tintinhull, near Martock, Somerset. The Orders came into operation on Wednesday.

* As Diseased or Exposed to Infection

CITY OF SHEFFIELD, REPORT OF THE CHIEF VETERINARY INSPECTOR, FOR THE YEAR 1910. [ABSTRACT].

Veterinary Staff.—During the year there was a staff of three qualified Veterinary Surgeons, occupied as follows:—In the inspection of dairies and cowsheds in the city and examining the udders of cows in the city cowsheds, or in country cowsheds from which diseased or suspected milk has been sent into Sheffield; in inspecting meat, meatshops and slaughterhouses; in carrying out the veterinary and administrative work in connection with the Diseases of Animals Acts; and in the veterinary supervision of the Corporation stud of horses.

Tram and other accidents.—Seven cases of alleged damage to horses, due to tram accidents, have been investigated, and reports made on each to the General Manager of the Tramways. In connection with some of these cases repeated visits had to be made.

Meat and Food Inspection.—Fifty-seven and a half carcasses of beef were condemned during 1910 as being affected with tuberculosis. Four were beasts bought by the butchers as sound animals, which when killed were found to be suffering from Tuberculosis; Thirteen and a half were the carcasses of cows whose milk was found to contain tubercle bacilli; 40 were old worn out cows.

The total weight condemned during the year was 26 tons 19 cwt of meat; 14 tons 10 cwt of fish; and 1 ton 10 cwt of fruit and vegetables. It should be pointed out that the latter figures do not include unsound fruit and vegetables dealt with at the Wholesale Market, where it is made a custom of wholesale dealers to sell questionable fruit, &c., to hawkers *subject to sorting*. This custom does not appear satisfactory from any standpoint, and was reported to the Health Committee in September, 1910. It would appear that the Markets Department should provide a room where this sorting could, if necessary, be done under supervision.

During the year two Magistrates' Orders were required for the condemnation of bad meat. Two prosecutions were ordered by the Health Committee, one defendant being fined £20 including costs, and the other £7 including costs.

Dairy Inspection.—In addition to examining the udders of the milking cows in the city cowsheds, the Veterinary Inspectors inspect the sanitary conditions of the cowsheds, dairies, and milk vessels, and take note of the cleanliness of the cows, also of the feeding and general management. In the case of poor samples of genuine milk found by chemical analysis, enquiries, sometimes of a protracted nature, are made into the principles and methods of feeding the cows, and friendly advice is given to assist the owners to improve the quality of the milk. Over 1,000 visits were made to dairy farms within the city. Five new cowsheds were built during the year, giving accommodation for 36 cows, also five new wash houses for sole use in connection with dairy work.

Tuberculosis and Milk.—During the year, 336 samples of mixed milk coming into Sheffield by rail or road conveyances were taken for bacteriological examination, 35 of which, equal to 10.4 per cent., gave a positive result, whilst 301 were negative.

In following up the 35 tuberculous samples 36 farms were visited, and the udders of 616 cows examined. At 23 of these farms 27 cows with tuberculosis udders were found. At the remaining 13 farms no cows with tuberculosis udders were found, and subsequent control samples of the mixed milk from these farms were proved negative by bacteriological examination. In most of these instances the farmers had sold cows off the farms during the period intervening between the taking of the tuberculous mixed sample and the date of the inspection.

Two notifications were received from farmers outside the city, and one cow was proved to have a tuberculous

udder. One mixed sample was found to kill the experimental animals by diplococcic infection, and, in following this up, 34 cows were examined, and one cow having a tuberculous udder was found. If we take the percentage of 29 tuberculous udders amongst the 760 country cows clinically examined, the figures work out at 3.8 per cent.

The number of cowshed premises inside the city is 228, and the number of cows housed in those premises is about 2,400. Allowing each cow to be in a city cowshed eight months, it follows that about 1,200 fresh cows must be added to that number, making 3,600 in the city cowsheds to be examined during the year. The number of inspections of city cows made during the year was 9,573, and 22 cows having tuberculous udders were discovered—equal to a percentage on 3,600 of 0.6. These figures are interesting as shewing the percentage of cows having tuberculous udders likely to be found amongst dairy stock, should veterinary inspection of such cattle become general throughout the country, which, in any legislative measures that may be introduced for the eradication of Tuberculosis amongst cattle, would be essential for success.

Fifty-one cows definitely proved to have tuberculous udders were disposed of as follows:—5 were sold by the owners and lost sight of; and 46 were killed, the carcasses of 27 being passed as fit for human food after the diseased parts had been first removed and destroyed, and 19 totally condemned and the carcasses destroyed at the destructor or knacker's yard.

Four farmers were summoned before the Health Committee to show cause why an order should not be made (Section 135 of the Sheffield Corporation Act, 1900) requiring them not to supply any milk from their dairies for consumption within the city. In two cases orders were made but were not enforced, as the farmer either killed the tuberculous cow or supplied information as to its slaughter. In one case no order was made, as the farmer had stopped sending milk to Sheffield, whilst in the fourth case no order was made, two cows with tuberculous udders being killed, but the farmer was prosecuted for failing to notify, a fine of 20/- including costs being imposed.

DISEASES OF ANIMALS ACTS, 1894-1909.

Anthrax.—Twelve suspected outbreaks of Anthrax were reported on premises in the city. The disease was found to exist in all the cases except one. In five instances the disease was discovered in the carcasses of animals slaughtered *in extremis* by the owners and sent into slaughterhouses in the city to be dressed by butchers. Two of these came from farms in the county of Derby, two from farms in the West Riding of Yorkshire, and one from a city cowshed (butcher's premises). The other six animals affected died on premises in the city, and were notified by the owner or his veterinary adviser. Two of the animals died in the same field, but with an interval of more than two months between. All but one of the diseased animals were cattle, the other being a horse. In two cases the Health Committee ordered prosecutions, one defendant being convicted of two offences, and fined £5 and 10s. respectively, with £1 1s. costs, and the other being fined £10 inclusive.

Parasitic Mange.—Thirteen outbreaks of this disease in studs in the city were dealt with during the year. Several were notified by the inspectors of the Sheffield Society for the Prevention of Cruelty to Animals. Sixteen horses and one donkey were affected. All were isolated, medically treated, and eventually cured. Four of the cases occurred on two stable premises belonging to one firm, and required continued official inspection for periods of three months and four months respectively.

Swine Fever.—One hundred and sixteen cases of illness or death of pigs were reported during the year. In 3 cases the symptoms or post-mortem appearances were

suspicious of Swine Fever, and the cases were consequently reported to the Board of Agriculture and Fisheries in compliance with the Swine Fever Order. These cases were investigated by the Veterinary Inspectors of the Board, but none of the cases were confirmed as Swine Fever.

Foreign Dogs.—During the year 80 foreign dogs were licensed into the city. They belonged to 10 different owners, and all but 9 were dogs performing at Sheffield music halls. Twenty visits were paid to see that the Board of Agriculture's conditions were being complied with by the owners. Nine dogs, 23 wolves, and 4 jackals, were licensed by the Board of Agriculture to Messrs. Bostock's Jungle at the Alexandra Rink, Townhead Street, at various times, and repeated visits were made to inspect them.

Animal Transit.—Over five hundred and twenty visits were made to the railway stations and cattle landings for the purposes of the Animals (Transit and General) Order of 1895, the amending Order of 1904, and the Conveyance of Horses Order of 1909.

Horse Sales.—The weekly auctions of horses and the horse fairs have been regularly visited as required by the Glanders and Farcy Order of 1907.

The Report is signed by J. S. LLOYD, F.R.C.V.S., D.V.S.M. Viet., *Chief Veterinary Inspector*.

The Veterinary Profession and State Grants.

On this subject Mr. Charles Bathurst, M.P., writes to *The Times*:

"For the Government of a country, which boasts both of its wealth and of supplying the world with the best of its live stock, to make a smaller annual subsidy for the above purpose than the smallest of the German States is little short of a public scandal. Our live stock, the veterinary profession, and human health all alike suffer in consequence. A duly qualified veterinary surgeon requires as thorough and therefore as costly an education as a physician. In Great Britain there is neither inducement nor sufficient opportunity given to animal doctors to obtain it, with the result that capable and ambitious young men do not readily adopt this profession, and (except now in the Army) the latter does not enjoy the social status which is its due. Hundreds of thousands of farm animals die annually from recognisable diseases without any veterinary treatment, owing to the inaccessibility of, or lack of confidence in, the nearest veterinary practitioner; thousands of others die from diseases which cannot with certainty be diagnosed. Yew poisoning is not uncommonly given as the cause of bovine mortality after treatment of the animal for some other ailment. No disease common to farm animals and man is more deadly than anthrax; our coroners are not unfamiliar with cases of human deaths consequent upon handling stock which have been declared upon diagnosis to be otherwise diseased. Although a drastic Milk Bill based upon the Final Report of the Royal Commission on Human and Animal Tuberculosis is about to be introduced into Parliament in the coming Session, no one can say that it has yet been conclusively proved that bovine tuberculosis is identical with, or commutable into, the human disease, or variety of diseases, which pass under the same name. In the present uncertain state of knowledge a few thousand pounds spent upon continued investigation into this problem by highly qualified veterinary experts, with a view to the prevention of consumption, would be better employed than either the millions about to be expended under the National Insurance Act on its attempted cure in palatial sanatoria, or the hundreds of thousands which county ratepayers will be asked to contribute by way of compensation for cattle slaughtered as dangerous to human life because, possibly, they react to the tuber-

culin test. Owing to over-hasty legislation based on insufficient knowledge there is the possibility of a milk famine producing more infantile consumption than myriads of bovine germs.

The enormous national expenditure upon, and the continued prevalence of, swine fever are, in the light of Continental experience, directly traceable to lack of State subsidised research. Although, amid other most tiresome restrictions upon the swine industry, twenty-eight days have been fixed for several years as the period for isolation prescribed by the Board of Agriculture, its chief veterinary officer was compelled to admit while cross examining one of the witnesses before the Swine Fever Departmental Committee, that the period of latency, and therefore of communicability, of this was still unascertained, but was probably far in excess of the above period.

I hesitate to say much about foot-and-mouth disease, as the matter is at present *sub judice*; but it is, to say the least, unsatisfactory that through ignorance of the aetiology of this disease the policy of wholesale slaughter and most drastic isolation are admittedly the only possible present safeguards against a devastating epidemic which would render butchers' meat (as it has recently in Germany) the luxury of the rich.

The same may be said of the mysterious Johnie's disease (so often mistaken by veterinary surgeons for tuberculosis), the prevalent intestinal strongyle disease of sheep, and contagious abortion in cattle, all of which are causing serious loss to stockowners and creating an urgent desire for more precise scientific knowledge on the part of veterinary practitioners. —*Farm and Home*.

Mendelism.

"Know anything about Mendel's law?" he asked, coming in from the byre. "Here have I a calf just born which entirely contradicts it. Its mother is a pure red, and further back for three generations pure red; the bull is red, and his dam was red, and as far back as I can trace his ancestry, he comes off a red breed. And here comes a calf to-day pure white. What would Mendelism make of that?"

"But what is Mendel's law?" I asked.

"Well!" rubbing his head: "doesn't it say that heredity goes by certain exact laws. . . . It's supposed to help breeders. . . . I am not breeding for any special line. . . . but there's that white calf. . . . No one could have expected it."

Now, I had once made a half-hearted effort to comprehend the Mendelian principle of heredity, and was stopped short by an algebraic formula which reminded me of my school days, and the school-day habit of brain has long departed from me, but some confused memory prompted the suggestion—

"Perhaps the white colour is a recessive character from some far-back white ancestor."

"But, look here! Don't we get blue greys by crossing a white with a black? So, in that case, neither white nor black is a dominant character."

"But we're no nearer Mendel's law, and it should be easy for us, surely, to get at it somehow."

"Look up that Encyclopædia, then, while I have a turn round the sheep."

Mendelism. See *Heredity*. Pages upon pages about heredity: Weismann's theory, germ-plasm, etc. Then we come to Mendel's Law, and I patiently and expectantly read through an interminable paraphrase setting forth how this Law has made clear the dark places for the breeder, enabling him to . . . and so on. Once we thoroughly master the intricacies of this law, we shall be "in a position to remake continually any good potato." . . . By the time I got to the law itself, it was growing dusk, and how rapidly it darkens in December, however close one presses to the window!

"Got it read up?" "he asked a little later at tea.
"No-o!" I said weakly; "it grew dusk. After the children have gone to bed, perhaps. You read it yourself, and explain it to me."

"Well, I will some night. But I have a lot to do just now. New cowman. Shepherd off with bad hand. Head gets muzzy when I sit down before a warm fire at nights. There's too many things connected with farming. A man can't keep up with them all."

In a review of Professor Punnet's "little manual" on Mendelism, I learn that "every good citizen should make it his business to be as familiar with its principles as his capacity permits" (this, because of its bearing upon eugenics). "Capacity permits" sounds just a little alarming. However, I suppose I shall have to have another try, or the world will be getting out of hand with me.—*Scottish Farmer*.

Donations to R.C.V.S.

The Secretary of the Royal College of Veterinary Surgeons begs to acknowledge the receipt of the following donations to the College funds, from Messrs.

P. G. Bond, Plymouth	£1	1	0

ARMY VETERINARY SERVICE.

The undermentioned officers embarked in Transport "Rewa" at Southampton on Jan. 10th, for a tour of service in India:—Capts. G. T. T. Jackson and A. J. Williams.

Capt. T. A. Nicholas proceeded to Egypt on Jan. 4th for duty with the Egyptian Army.

OBITUARY.

JONATHAN VINCENT, V.S., Needham Market, Suffolk.

Mr. Vincent died on Jan. 6th, at the age of 91 years.

EXPORT OF LIVE STOCK AND VETERINARY DUTIES.

Sir,

In the report of the Departmental Committee on the British Export Trade in Live Stock (appointed by Lord Carrington, March, 1910), there are some points of interest to veterinary surgeons.

From the description of the character and extent of the trade it is evident that there is a great demand for the best classes of British live stock in many colonies and foreign countries, and also that large fluctuations occur in the demand.

In considering the question of the extension of this trade the Committee have made many excellent recommendations, e.g. the co-operation of various Breed Societies in advertising schemes, the distribution of translations of the Board of Agriculture handbook on British breeds of live stock in foreign countries. Also the keeping of milk records in England and their publication abroad.

Section V. on p. 14 of the report is, however, of the most interest to the veterinary practitioner. It is proposed to extend the trade by establishing a Government Testing Station to which, at the expense of the vendor, animals to be exported must be sent for five weeks for examination and to undergo the tuberculin test. This regulation, of course, only applies to cattle, and it is supposed that the official test will give the foreign buyer confidence in his bargains.

The cost of the test is estimated at about £5 or £6 per head, to which must be added the railway charges, in some cases amounting to another £3 or £4 for each animal. If an animal reacts the owner would have to pay the fare back to his farm, and the tubercular bull would be sold to a British farmer at a low price.

Some years ago, when staying with a veterinary surgeon, qualified 25 years ago, I assisted him to test a number of pedigree bulls for export to Argentina. The agent of the South American buyer inspected the animals and then sent his own temperature charts to be filled in, and insisted on the use of tuberculin obtained from the Pasteur Institute. The veterinary surgeon was well paid by the buyer of the animals, and these tests were a source of annual income to him. The bulls were again tested on arrival, but there was but little chance of infection *en route*.

Against this pars. 72 and 73 (p. 33 of report) look well.

"72. The criticisms which were made as regards the veterinary profession are partly due to circumstances which have been unavoidable. The tuberculin test is of comparatively recent introduction, and it was not known when a large number of the veterinary surgeons who are now in practice underwent their technical training. The institutions which grant diplomas are now well equipped, and the Royal Veterinary College, for instance, receives a considerable grant of public money, which has, moreover, been recently increased. In this connection the Committee is of opinion that the attention of the various educational bodies concerned should be drawn to the commercial importance of the tuberculin test, and to the desirability of providing careful practical instruction in its application."

"73. The standardisation and State control of tuberculin have already been considered by the Royal Commission on Tuberculosis which recommended that funds shall be placed at the disposal of the Board of Agriculture and Fisheries for the preparation of the commercial article, and that it should be supplied gratuitously to stockowners."

Probably both the expert veterinary witnesses, Messrs. Villar and Manuel qualified before the introduction of this test. Yet the comparatively new Schmidt's treatment of milk fever will be familiar to both of them, and it is reasonable to suppose that other members of the profession have also kept in touch with new methods. Of what use is a veterinary surgeon's education if it does not enable him him to adapt himself to so simple a test as that under consideration. Note also that the Royal Commission on Tuberculosis advised the free distribution of the reagent "Tuberculin" to stockowners at the expense of the State.

A perusal of the instructions issued with the tuberculin supplied by the Royal Veterinary College will show that the test is not impossible for a practitioner to work in between his rounds, and also the sale books of that Institution would, I think, show that it is very widely used by veterinary surgeons.

The added note by Mr. Middleton of the Board of Agriculture and Fisheries is a curious feature of the report. He is not a veterinary surgeon, yet he writes strongly in favour of the proposed Government station, and amongst other arguments in support of his case the facts that

"By means of a vaccine prepared by the Chief Veterinary Officer to the Board of Agriculture and Fisheries, it is now possible to protect cattle from attacks of the very fatal disease known as redwater."

And also that

"Already, it is possible to protect horses against biliary fever, a disease which claims many victims in South Africa, and there can be little doubt that if facilities for immunising animals were provided at an official station the method would soon assume importance, and would prove of much use to breeders and exporters of livestock."

Would it be generally admitted that these two facts are well enough established to be used as arguments by a layman?

Apologising for the length of this letter.—I remain, yours, etc., GEO. L. Y. INGRAM.

P.S.—Report, price 5d., can be obtained from Messrs. Wyman.

(Owing to pressure on space the foregoing has been held over.)

A convenient and efficient
Embrocation.

Capsolin (P., D. & Co.)

is composed of capsicum, camphor, oil of turpentine, oil of cajuput, and croton oil, so blended with an emollient base as to ensure an active degree of counter-irritation without vesication.

A small quantity rubbed into the affected part till absorbed forms an excellent substitute for mustard poultices or hot fomentations, and is of great value in cases of

Capped Hoof.	Rheumatism.
Inflamed Joints.	Sore Throat.
Periostitis.	Strangles.
Pleurisy.	Strained Tendons.
Pneumonia.	Synovitis.

Being free from poison it may be used with safety in parts which the animal may be inclined to lick.

A soothing and healing
Dressing.

Emollientine (P., D. & Co.)

is a combination of aluminium hydrate, carbolic acid, isarol, lead oxide, corrosive sublimate, and zinc sulpho carbolate, which is exceptionally successful as a means of reducing inflammation, mitigating pain, maturing suppurative processes, stimulating cell action, and promoting healing. It forms a most beneficial application in

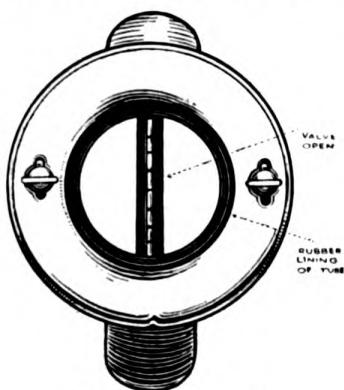

Canker.	Mud Fever.
Cracked Heels.	Over-reach.
Garget.	Saddle Galls.
Grease.	Sore Shoulders.
Incised Abscesses.	Sprains.

Its bactericidal properties render it most effective in eczema, psoriasis and other parasitic diseases.

Practices for Disposal

KENT. For immediate sale, an old established practice owing to vendor's illhealth. Represented as having returned for several years between £300 and £400 per ann., at little expense. PR. 108.

BUCKS. A good opportunity for a young, qualified V.S., to secure a well established practice, represented as returning (cash) £300 p.a., on average for 16 years. Vendor retiring from profession. Good 8-roomed house and garden, stabling, etc. at £30 p.a. To effect early sale vendor will accept £100. PR. 188.

SOUTH MIDLANDS. A good-class practice in a first-rate sporting district is for immediate disposal. Satisfactory reasons for relinquishing. Returns represented as being over £450 p.a. PR. 119.

EASTERN COUNTIES. An old established practice in good agricultural district is for disposal. Represented as returning about £450. Low inclusive price for quick sale. Nice house and stabling, large paddock. PR. 118.

HAMPSHIRE. A partner required for old established practice in fashionable sea-side resort. Returns represented as close on £700. Premium for half share £300, which can be paid by instalments if necessary. PR. 434.

CHANNEL ISLAND. An opportunity for acquiring the nucleus of a practice represented as returning about £175 p.a. Great scope for increase. Easily worked at little expense. An offer of about £50 would be accepted for immediate sale, vendor having secured an appointment. PR. 120.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The **"Record"** Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindrical form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND MINIMS.

Principal and Dean : Professor **SIR JOHN M'FADYEAN, M.R.C.V.S., M.B., B.Sc.**

Membership Diploma of the Royal College of Veterinary Surgeons :

Complete Courses of Instruction are conducted in all the Subjects of the Examinations for this Diploma. The facilities, etc., afforded for the Practical Training of Students are unrivalled.

Bachelor of Science Degree, University of London.

The Professors of Chemistry, Biology, Anatomy, Physiology, Hygiene, and Pathology, are Recognised Teachers of the University, and conduct in their respective subjects courses which qualify for the Science Degree (B.Sc.), which may be taken concurrently with the above Diploma.

POST GRADUATE COURSES.

These Courses in Veterinary Pathology and Bacteriology are conducted under the supervision of the Principal and are specially adapted to the requirements of officers of the Army Veterinary Department, Colonial Veterinary Surgeons, Veterinary Inspectors under the Contagious Diseases of Animals Acts, and Candidates for the Fellowship Diploma of the Royal College of Veterinary Surgeons.

The number of places for these Courses is limited and early application must therefore be made to prevent disappointment. The next Course will begin on Monday, October 7th, and terminate on Friday, November 29th, 1912.

The College Calendar, containing full particulars, will be forwarded on application to

The Secretary,

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1228.

JANUARY 20, 1912

VOL. XXIV.

THE COUNCIL MEETING.

Not much comment need be offered upon the Council meeting. First we touch upon its most important and also most depressing portion—the discussion of the College finances, which, indeed, might almost be left to speak for itself. Last July £1000 worth of consols were sold, and much of the proceeds went to repay a previous heavy bankers' overdraft. To-day the treasurer has but £150 left in hand, which means that very shortly the Council will be faced with the alternative of selling more consols or recommencing to overdraw. The discussion upon this position is worth careful reading.

The view of the majority of the Council is quite clear—they object to asking members for donations on principle, as "making the willing horse pay," and therefore they will not issue an appeal to the profession. At the same time they evidently do not feel justified in declining donations offered unasked, for the few sent this quarter have been accepted with thanks, as before.

The moral to be drawn is—let those who are willing to stay the College a little on its course towards bankruptcy continue to send their cheques.

Little else in the report calls for notice. The Parliamentary Committee reported upon a great deal of work, most of which is already known; and we have the satisfactory assurance that the Council's opinion will receive full consideration from the Home Office in connection with the projected drawing up of regulations for the inspection of animals under the Coal Mines Act. A single omission has caused the long list of alterations in the examination bye-laws, of which notice had already been given, to be suspended for another three months. Their text is published, and there is ample time to discuss them before April.

Two little items illustrate the growing recognition of the profession overseas, viz., the receipt by the Council of an Ordinance for the Registration of Veterinary Surgeons for the Island of St. Vincent, and an Act to regulate the practice of veterinary surgery in Western Australia. Both documents are now in the College archives, and members contemplating emigration to either of these places may thus gain direct information regarding the conditions of veterinary practice there.

Lastly, this year, as was first made possible by the Supplementary Charter of 1876, the annual general meeting is to be held in Dublin. This is a well-merited compliment to the President, and there are other reasons to commend the step. It will give our Irish colleagues a chance of showing their individual interest in the affairs of the Body Cor-

porate, and we should not be surprised to see them do so in better numbers than is the wont of those practising in or near London. The attendances at the London meetings are a disgrace to the profession; that at Dublin may be very different.

THE KIRK APPEAL CASE.

The Kirk appeal case is over; and three judges have unanimously decided that veterinary surgeons who wish to use the College crest must pay for doing so. This decision was foreshadowed by the expert advice given to the R.C.V.S. some time ago. The commendability or otherwise of using the College crest is largely a matter of opinion; our own is that the practice might advantageously be dropped. Very few members are likely to think the crest worth the annual payment of a guinea; and the local authorities will probably gain very little from the L.C.C.'s successful appeal. The veterinary profession, we think, has lost still less by the result. But we should be glad to see further support given to the fund for the defence. Mr. Kirk has done a service to the profession, and has to bear the costs of his unsuccessful fight. When so many of our members have hitherto used the crest, the man who has indirectly aided all should not be allowed to lose by it.

PARALYSIS OF THE SOFT PALATE IN THE DOG.

Hebrant and Antoine record the case of a three-year-old draught dog, which was brought to them for observation soon after being purchased. The animal was well built, and strong enough to draw a very considerable load; but was quite useless for draught purposes, on account of "roaring." As soon as he made an effort just sufficient to very slightly accelerate the respirations, he commenced to roar very intensely, which prevented all further effort, and rendered him useless for work.

When the dog was examined at rest nothing abnormal could be discovered. The respirations were calm and deep, and no sound of roaring could be heard. No abnormal conformation of either the nostrils or the pharyngeal region was visible.

In movement, however, the animal only travelled a few yards before commencing to roar. By careful observation, it was found that the roaring noise was only audible when he respired through the mouth. As soon as the mouth was closed and the dog respired by the nasal cavities, all roaring ceased; and he could travel some time without a renewal of it—until, in fact, the respirations became accelerated and he was obliged to open the mouth to admit air.

A minute examination of the interior of the back of the mouth and the pharynx was then made. No inflammatory lesion was discovered; but the attention was immediately arrested by the flaccidity and exaggerated length of the soft palate, which covered a portion of the glottis. It could easily be displaced from that position, being so inert as to offer no resistance.

The diagnosis, therefore, was one of paralysis of the levator muscles of the soft palate. So long as the dog respired by the nasal passages, the respiration was effected without abnormal sound, no obstacle existing to the passage of air. But as soon as the animal had exerted himself sufficiently to require buccal respiration, then the column of air, in inspiration and expiration alike, struck the inertly floating soft palate and thus caused the sound of roaring.

The cause of the condition could not be discovered. Revulsive treatment was applied to the throat, and nervous stimulants given internally, but all treatment failed completely. Nothing could be done, therefore, but advise the client to get rid of the animal as useless for work.—(*Annales de Méd. Vét.*)

THE STRUCTURE AND STAINING OF TUBERCLE BACILLI.

Julius Schmiedhoffer says (*Allatorrosi Lapok*) that the acid-fast character of the tubercle bacillus is due to the molecular structure of the bacillus, and not, as has been supposed, to a special envelope of fat or nuclein. Even when treated with alcohol, ether, xylol, chloroform, benzine, acetone, carbon sulphide, or liquor potassæ, tubercle bacilli appear acid-fast.

The author's researches indicate that the tubercle bacillus does not belong to the bacteria which multiply by spore formation. The bodies which some authors have regarded as spores are really aggregations of chromatin, which become visible through the degeneration of the envelope. They play no part in the reproduction of the bacillus; present none of the characters of an independently developing body, and perish with the bacillus, or at an earlier period. They never appear independently, either in pus or cultures.

The author has also undertaken investigations to compare the value of the older and newer methods of staining tubercle bacilli, and finds that the Ziehl-Neelsen procedure still cannot be replaced for the quick demonstration of the bacilli in either discharges or cultures. It is decidedly the simplest method, and renders especially good service in cases in which the discharge contains many other species of bacteria; but it is not at all adapted to structural investigations. For the latter purpose a modification of Gram's method is most applicable, the modification being that the decolourisation is carried out, not with alcohol, but with either acetone or a mixture of equal parts of acetone and alcohol.—(*Berl. Tier. Woch.*)

W. R. C.

Royal College of Veterinary Surgeons.

A quarterly meeting of the Council was held at the College, 10, Red Lion Square, London, W.C., on Friday afternoon, 12th January, 1912, Professor A. E. Mettam, the President, occupying the chair. The following members of Council were present: Col. Sir Francis Duck, K.C.B., Major-General Thomson, C.B., Profs. Bradley, Dewar, McCall, Sir John M'Fadyean, and Shave, Messrs. Abson, Banham, Barrett, Carter, Garnett, Hobday, Lawson, Lloyd, McL. McCall, Mulvey, Roberts, Shipley, Slocock, Stockman, Sumner, Trigger, and Wharam; Mr. G. Thatcher, (solicitor), and Mr. F. Bullock (secretary).

The PRESIDENT: Gentlemen, may I first offer you from the Chair hearty greetings for the New Year, and hope that the coming year will prove one of success to the College, and that the end of the year may see the College in a better and more flourishing condition than we know it is in at the present time. I have great pleasure, gentlemen, in wishing you the compliments of the season.

Mr. MULVEY: The same to you, sir. (Cheers.)

MINUTES.

On the motion of Prof. Dewar, seconded by Mr. Abson, the minutes of the last meeting were taken as read and confirmed.

APOLOGIES FOR ABSENCE.

The SECRETARY announced that apologies for inability to attend the meeting had been received from Mr. Dunstan, who had met with an accident, Mr. McKinna, Mr. Mason, and Mr. Rutherford.

The SECRETARY read the obituary list.

ADMISSIONS TO MEMBERSHIP.

The SECRETARY read the following list of members who had been admitted since the previous quarterly meeting of Council:

Dublin College.—Messrs. R. P. Byrne, R. Devereux, J. T. Evans, V. Fox, J. J. G. Keppel, R. Marner, P. W. D. O'Connell, W. J. O'Donoghue, A. O'Neill, W. E. Phipps, T. L. Shea, F. J. Shearman.

Glasgow College.—Messrs. J. Gibson, J. Scott.

Edinburgh College.—Messrs. G. Currey, S. C. Currie, J. R. Greig, T. F. Sexton.

Liverpool College.—Messrs. E. L. Butters, D. R. F. Hoddinott, H. D. Lewis.

London College.—Messrs. F. E. Heath, C. Holland, E. J. Lainé, C. W. Perrin, S. Smith, H. Stephenson, B. M. R. West.

CORRESPONDENCE.

The SECRETARY read the following letter from Mrs Owen Williams:—"Would you please to convey to those members of the Council who so kindly sent me the touching message of their sympathy in my deep sorrow my most heartfelt thanks."

The SECRETARY read the following letter, dated October 18th, 1911, from Mr. A. M. Trotter, Secretary of the Association of Veterinary Officers of Health:—"I was instructed at the annual meeting of the above Association to forward for the consideration of the Council of the R.C.V.S. the annexed resolution, and to express the hope that they would see their way to carry out the suggestion. I need hardly add that the importance of meat and milk hygiene warrant the adoption of the course suggested."

Resolution.—Resolved: That the members of the Association of Veterinary Officers of Health beg the

Council of the Royal College of Veterinary Surgeons and the Governing Bodies of the various Veterinary Colleges to consider the advisability of treating those branches of the profession relating to public health—meat and milk hygiene—as a special subject."

The PRESIDENT: Accompanying the communication that Mr. Bullock has read is a printed circular, which I presume the majority of the members of the Council, if not all, have already seen. It practically is an extended account of the transactions occurring at this meeting of the Association of Veterinary Officers of Health. Will the Council be pleased to say what is to be done with this communication from Mr. Trotter. Will you refer it to some Committee for consideration and report?

Mr. LLOYD: I propose that the letter be referred to the Examination Committee for consideration and report. That is the Committee which deals with the examination of the students.

Prof. McCALL: I beg to second that.

Mr. STOCKMAN: As an amendment, I would like to propose that we ask for some indication from the Association on what lines they propose action should be taken. I have read the statement, and I think I am quite prepared to agree with some parts of it, but I understand that we have already provided teaching in these subjects. Therefore if they could indicate from their special knowledge what they think the curriculum is deficient in, it might be of some help.

Prof. McCALL: Could not the Committee make that enquiry direct?

The PRESIDENT: I scarcely took what Mr. Stockman said as being an amendment to Mr. Lloyd's motion.

Mr. STOCKMAN: Yes, I meant it as an amendment.

The PRESIDENT: I think what you said is no amendment unless you move it in specific words. The motion is that it should be referred to the Examination Committee. Would not that meet what you require?

Mr. STOCKMAN: Yes, there is no harm in doing that. The Examination Committee can report. I suppose the Examination Committee can communicate with the Association.

The PRESIDENT: Yes. It is proposed and seconded that the letter be referred to the Examination Committee for further enquiry and report.

The resolution was unanimously adopted.

PRESENTATIONS TO THE LIBRARY.

The SECRETARY announced that the following presentations had been made to the Library since the last meeting of Council: By Major F. S. H. Baldrey, F.R.C.V.S.: "Sensitised Vaccine in Haemorrhagic Septicæmia"; "A Cultured Method of Hyper-Immunising Animals for the Production of Anti-Rinderpest Serum"; "The Evolution of *Trypanosoma Evansi* through the Fly: *Tabanus* and *Stomoxys*"; "An Undescribed Organism—Pathogenic to Laboratory Animals, Cattle, and Sheep; and Simulating Blackquarter in its Pathogenicity." Annual Report of the Bengal Veterinary College and of the Civil Veterinary Department, Bengal, 1910-11; Report on the 9th International Veterinary Congress at the Hague, 1909, per Mr. G. A. Banham, F.R.C.V.S.; Report on Higher Education in the State of New York for 1910; Catalogue of Exhibits in the British Section of the International Shooting and Field Sports Exhibition, Vienna, 1910; *The Rhodesian Agricultural Journal*, October, 1911; *Revue de Pathologie Comparée*, October and November, 1911; Bulletin of the Sleeping Sickness Bureau, November and December; Bulletin of the Yellow Fever Bureau, October, November, and December, 1911; *The Journal of the Board of Agriculture*, October, November, and December, 1911; Leaflets of the Board of Agriculture and Fisheries; *The Journal of Tropical Veterinary Science*, Vol. VI, No. 4; *The Journal of Comparative Pathology and Therapeutics*, December, 1911; *The Journal of*

Meat and Milk Hygiene, October, November, and December, 1911; *The Veterinary Journal*, *The Veterinary News*, and *The Veterinary Record* for the quarter; *La Tuberculose*, August and September, 1911.

On the motion of Mr. Carter, seconded by Dr. Bradley, a hearty vote of thanks was accorded to the respective donors.

FINANCE COMMITTEE.

Mr. ABSON read the following report of a meeting of the Finance Committee held on Friday, January 12th, 1912:

Chairman. In the absence of the Chairman, it was resolved that the President be appointed to the Chair.

Minutes.—The minutes of the previous meeting having been printed and circulated, were taken as read and confirmed.

Donations. The Secretary reported the receipts of donations from members for the year 1912, amounting to the sum of £5 5s. It was resolved that the donations be accepted with thanks.

Financial Statement. The Treasurer submitted his financial statement for the quarter. It was resolved that the financial statement be approved, and that the Treasurer be authorised to pay the liabilities shown, together with cheques for monthly salaries, petty cash, insurance, gas and electric light, and delegate's expenses, Glasgow.

Mr. ABSON: I beg to move the reception and adoption of the report.

Mr. ROBERTS: I beg to second that.

The PRESIDENT: It is now open for discussion.

Mr. MULVEY: Gentlemen, the position of Treasurer of the Royal College of Veterinary Surgeons is a most unpleasant one to occupy in its present financial condition. You will notice from the balance sheet that, after our liabilities have been paid, we shall have a balance of £150 18s. 11d., but when we have paid certain accounts and liabilities that will be incurred before our next meeting there will be only £111 12s. in hand. In addition to that, up to the end of March there are certain other liabilities which will occur before we meet again which amount to another £147 at least, and that figure does not include any expenses that may be incurred during the following quarter of April to June. It is very difficult to meet an expenditure of £147, or probably £150 or £160 with a balance in hand of only £111 12s. You are aware that it was only in July last that we sold out £1,000 worth of Consols, which reduced our income by £23 11s. a year. If we keep on selling Consols—and I see no other way that we can adopt in order to carry on the work of the College—the income from that source will soon be done away with altogether. How is this to be met? Is it possible to reduce our expenses? (Cries of "No.") Certainly the Finance Committee have gone carefully through them with a view of reducing everything that was possible, and personally I do not see any way in which they can be made much less. I do think it ought to go out from this Council to the profession that the time has almost arrived when it will be impossible for us as a Council to undertake prosecutions on behalf of its members. We cannot work without funds, and unless funds are provided we shall have to come to a standstill in that way. I do not know what to suggest. Certainly we cannot make our expenses less. The only thing is that our income must be increased in some way or other. Whether the proposed Bill will go through or not I do not know, at all events that is in the future, and very far in the future I am afraid. I can only leave the matter in that way, sir, except that I think authority should be given to me as treasurer to sell out, if necessary, another £1,000 worth of Consols.

Mr. TRIGGER: I would like to say a word, sir, on our very deplorable state of affairs. The Finance Committee

have threshed out the question of the expenses time after time. This morning he went through them carefully once again, and I am perfectly satisfied that they have been cut down to a point at which they cannot be cut down any further, unless we have honorary examiners in the same way that we have honorary Councilmen, but of course that is a thing you cannot expect. I would only venture to suggest to Mr. Mulvey that, rather than selling Consols at the present time, we had better wait for three months in order that we may see how we stand with our Bill. I do not think he will have to overdraw very much at the bank, and if we can go on till April I think we shall be able to get through with an overdraft of £50 or £60. I think we might wait till the April Council meeting before giving authority for the sale of another £1,000 worth of Consols, because in that way we shall get interest on the Consols for three months.

Mr. CARTER: Could not we make a general appeal to the profession again as we did last year? I think that would probably get us over the difficulty for the time being. There are many members who said that if this was levied voluntarily they would subscribe, and I think if our present position was mentioned in the papers probably we might be able to get some assistance in that way.

Mr. TRIGGER: We do not want to go to any expense in getting it.

Prof. DEWAR: I think my friend, Mr. Carter, is a little mistaken in his remarks he has made with regard to an appeal being made to the profession. I proposed that an appeal should be made to the profession, but the Council decided it should not be made. I do think the Council are hardly doing its duty. We cannot go on in this way for very long. Mr. Mulvey has told us that there is no guarantee that the Bill will be passed in the next session of Parliament; he did not use those words perhaps, but that is what I inferred from what he said. I do not know anything with regard to that, but I do think that we are hardly doing our duty unless we set the profession an example and appeal to the profession for assistance. We are going on diminishing our resources, and as my friend Mr. Rutherford said in his report to the Secretary about the meeting in Edinburgh, no company or business firm can go on in that way for any time; it would soon be a case of liquidation. It does look to me a little invidious if we appeal to the profession to subscribe and do not subscribe ourselves. I think we Members of the Council might subscribe something—it need not be a big sum—to show the profession that we are in earnest about it, and if that is done I have not the least doubt we should get assistance. If Mr. Carter will second that I will move that that be done. I do not wish to mention any sum. I think the sum that we could give personally would be a sum well within the means of every member here, but at the same time I think it is only right that we should do it seeing the way that the capital of the College is dwindling.

Sir John M'FADYEAN: I think we all appreciate to the full the gravity of the financial position disclosed by the Financial Statement, reinforced by the remarks that have fallen from the Treasurer. The gravity of the position would be serious enough even if we had reason to think it was only temporary, but I think we should be deluding ourselves and deluding the profession if we gave it out that this is a mere transient financial inconvenience. One knows that there is a large body of expenditure to which this Council stands permanently committed, namely, the safeguarding of our own interests, and the interests of the public in connection with the Veterinary Surgeons Act; and I ought perhaps to have mentioned as entitled to the first place our duties to the public in connection with veterinary education and the conduct of the examinations. The falling off in the income has been mainly due to the

diminished number of aspiring entrants to the profession, and I for one am unable to see the least ground for supposing that we shall ever go back to the times of, say, 10 or 20 years ago (hear, hear). I think when one realises these facts one sees that little is to be expected from an appeal to the profession. Are we to suppose that the business of the Council is only to be made possible in the future by voluntary subscriptions received from men here and there? I think not, and I know not what ground Prof. Dewar has for supposing that an appeal to the profession would bring in a very considerable sum of money over a period of years. The appeal that has already been made was not very encouraging in that respect. But I maintain that it is really an inequitable means of raising the sum of money necessary to make our income and expenditure balance. I wonder if Prof. Dewar will assent to the statement that probably every member of the profession could afford to pay the sum of £1 annually to enable us to discharge our duties to the profession and to the public. This is what we know the majority of us think, and that is the principle that is embodied in the Bill that we have already laid before Parliament. It is possible that that Bill will not go through during the ensuing session, but I do not see any occasion to despair that it will go through eventually, and at no very distant date. But at any rate I maintain that is the proper solution, and indeed the only solution of our financial difficulties. (Hear, hear). As bearing upon the question of making an appeal to the profession, I should like to point out that the present moment is highly inopportune. The profession is really already saddled with a very great financial responsibility. I suppose everybody sitting here knows what is the responsibility to which I refer; it is that connected with the holding of the International Veterinary Congress in London in the year 1914. Those who have taken upon themselves the responsibility of organising that Congress are now making an appeal to the profession to raise within the next two years a sum of £3,000, and I do not suppose anything less will suffice. In these circumstances, does it appear to anybody to be advisable to make a second appeal to the profession? The result probably would be that both of them would be entirely inadequate, and those are the facts which I think ought to go out from this Council to the profession.

Mr. CARTER: With all due respects to Sir John's remarks, I certainly think that the profession comes first—our own profession in this country. I think we ought first to look to our own home.

Mr. BARRETT: If I may I should like to make one or two observations upon this point. I should like to say at once that I sympathise entirely with the remarks that have fallen from Mr. Mulvey, that his position to-day is not a sinecure, in view of the unfortunate financial position in which we find ourselves. On the other hand, I am rather inclined to agree with the observations which fell from Prof. Dewar, and which were seconded by Mr. Carter, that perhaps the time has come when we might appeal to the profession for some temporary assistance in view of the difficulties in which we find ourselves. It seems to me that the Balance Sheet on the whole is not quite clear, nor were the remarks of Mr. Mulvey quite clear either, because from the observations which he made it might appear to the profession that during the past year or eighteen months we have had a deficit of at least £1,000, because he referred to the fact that £1,000 worth of Consols were sold some months ago, and we would have to sell some more if we were to meet our liabilities. I take it that is not quite the position of the matter. I understood from our President this morning that during the past two years or so we had lost, about £700 that is to say we were conducting the business of this College at an annual loss of about £350. Certain observations which were made at this Council last year came before the profession, by means of which the profession

were informed that we were losing money in carrying on the work of the College, and there were several members of the profession who came forward and sent their cheques in order to meet the deficit which had then been occasioned. I do not think that is hard upon them. I do not think it is derogatory at all to us that, as a Council, we should ask the members of the profession who are rich and who are willing to pay a guinea or two to carry on the work of the College that they should again come forward and help us as they did last year. I do not know exactly what was the sum subscribed last year, but I think it was roughly about £100. That was one third of the loss which we sustained during the year. I want to say one other thing, if I may, in regard to this matter, and I want to be very careful how I say it, because the opinions which I held two years ago have not in any sense altered. Sir John McFadyean said, was there any member of the profession who was not able to pay £1 a year? My honest conviction is that there are a good many members of the profession who cannot afford £1 a year; and there is no getting away from the fact that there is still some opposition in the profession to the measure which we desire to pass through the House of Commons; and there is no getting away from the fact that that opposition will be almost entirely allayed if two or three gentlemen who are sitting round this corner would be content with an annual subscription, say, of half-a-guinea a year rather than a guinea. Half-a-guinea a year would yield to the College roughly £1,500 a year. That will give us ample funds and to spare, and I cannot help thinking that wiser counsels even now should prevail in regard to this matter. The House of Commons next Session will be deeply engaged.

Mr. TRIGGER: I rise to a point of order. I think when Mr. Barrett was elected President he gave us to understand that he would give his whole-hearted support to the Bill as it then stood. He is now crying down.

Mr. BARRETT: Mr. Trigger does not appreciate the point.

Mr. TRIGGER: Oh yes, I do.

Mr. BARRETT: I gave the profession, whilst I occupied the chair, my most whole-hearted support everyone will admit that and I am going to give the profession my support now, but surely a member is not thereby precluded from saying in this room at this meeting, which is a meeting amongst ourselves—

Mr. TRIGGER: I beg your pardon; it is public to the profession. With great respect it is not a meeting amongst ourselves. What we say here goes to the profession.

Sir JOHN McFADYEAN: I should raise another point of order, and that is whether it is really in order in connection with the consideration of the Financial statement to suggest amendments of the Bill. I think we might, if that is open to discussion now, have a prolonged one, but I do suggest to you, sir, that it is out of order.

The PRESIDENT: It was going through my mind that Mr. Barrett is getting perilously near discussing the Bill, and I was wondering in my own mind whether he was not trespassing too far on that point. But still I could not say where the line was to be drawn between the discussion as to this appeal that has been proposed by Prof. Dewar and Mr. Carter. I thought that the argument he was using was an argument in favour of the appeal.

Mr. STOCKMAN: There is another point of order, sir. Is it a year since we fully discussed the question of whether half-a-guinea or a guinea should be the amount inserted in this Bill?

Mr. SUMNER: I think this is out of order, sir.

Mr. ABSON: The question of the annual fee as proposed in the Bill was thoroughly discussed, and has

been over and over again. The question as to whether it should be 10/6 or one guinea was brought forward: we discussed it *pro* and *con*, and it was practically unanimously settled that it should be one guinea. I think there were only about three dissentients. The election was fought upon it. It is raising a question again for discussion that is dead.

Mr. BARRETT: Whatever your ruling may be, sir, I should bow to it, but I submit with respect to you and to the meeting that I was not discussing any proposed amendments of the Bill at all. I was merely answering the point which was quite rightly raised by Sir John McFadyean. No one would be more sorry than I to give expression to any language which would in the least irritate the members who are sitting round this table. That is not my intention at all.

Mr. ABSON: It is a question as to whether it will jeopardise the Bill.

Mr. BARRETT: How can a discussion round this table in a friendly way jeopardise the Bill, especially if the object of that discussion is to induce peace?

Mr. ABSON: May we have a ruling on the point?

The PRESIDENT: It is more than twelve months ago since it was discussed.

Sir JOHN McFADYEAN: That is not the point, sir.

The PRESIDENT: That was the point Mr. Stockman raised as regards the question of how long ago it was discussed.

Sir JOHN McFADYEAN: I want a ruling on the point whether it is open to a member of this Council in discussing the balance sheet put before the meeting to suggest that the Council should go back upon its practically unanimous decision that the Bill should stand as it is?

Mr. BARRETT: I never suggested that at all.

The PRESIDENT: The question of the Bill does not arise at all on this report.

Mr. BARRETT: I have not ever suggested that this Council should go back upon its decision with regard to the Bill.

The PRESIDENT: You must drop the question of the Bill.

Mr. BARRETT: I have not dealt with the Bill at all, if I may say so with the utmost respect. Sir John raised the question quite rightly that there was not a member of the profession who could not afford to pay £1 annually, and I threw out the suggestion, in answer to that remark,—Is it desirable to stick to the £1 annually? Would not it be more diplomatic, wiser—would not it be more likely to ensure success—(interuption)—I trust you will allow me to complete what I have to say; you do not know what I was going to say. If you desire to prevent one from expressing one's honest conviction I will sit down.

Mr. TRIGGER: That is my point of order.

Mr. BARRETT: The President has not upheld you.

The PRESIDENT: Yes, I say you cannot discuss the question of the Bill, and what we have already decided with regard to it; you cannot go back upon that.

Mr. BARRETT: With the greatest respect I am not discussing the question of the Bill at all.

The PRESIDENT: With the greatest respect you are discussing the question as to whether it should be a guinea or half-a-guinea, and I maintain that that is a question dealing with the Bill.

Mr. BARRETT: I bow to your ruling, of course, sir; I am not going to raise any question of that sort to-day, and if you say I must not go on I will desist. But I want to say this, that I quite concur in the remarks which have fallen from Mr. Carter, that if this profession is capable amongst its members of finding £3000 for the International Congress then it ought to be the more able and the more willing to provide £350 for the work of this College. It is idle to pretend that it is derogatory to appeal to the profession, or that it would be

contrary to our dignity to let the profession know by circular or by some powerful means that the sum of £350 will pay for the deficit which has been occasioned during the past year. I will say no more than that. I shall support Prof. Dewar in his motion if he persists in it, and I think it might very wisely be adopted by this Council.

The PRESIDENT: It has been proposed and seconded that an appeal be made to the profession for subscriptions.

Prof. DEWAR: That is not all the resolution—and that the members of the Council agree to give a certain sum as an example.

The PRESIDENT: We are members of the profession, are we not?

Prof. DEWAR: You disagree, of course.

The PRESIDENT: Give me exactly the terms of your proposition.

Prof. DEWAR: I will write it down.

Mr. GARNETT: While Prof. Dewar is committing his motion to writing, I hope I may be allowed to say a few words on this question, because it is not the first time it has been raised before the Council. It is one of those red herrings that has been drawn before the profession for years, and you see the result. The willing horse will pay, and go on paying, to the great satisfaction of a lot of the members of the profession. Now that is not equitable. (Hear, hear.) It is a position that this Council has never taken up. They think that if the profession is to benefit by the proceedings of this Council that the benefits to the profession should be contributed by the body corporate, both in the Council and outside the Council—by every individual member of the veterinary profession. That is the stand that this Council, as far as my experience goes, has always taken up, and I think it would be a great pity to issue an appeal to the profession simply to mulct those enthusiastic members who are willing to support the profession, for the benefit of those who will not put their hands in their pockets, not only to help the body corporate but to help themselves.

Mr. ABSON: And many of whom are very well off, too.

Mr. GARNETT: Yes.

The PRESIDENT: Will you now read your motion, Prof. Dewar?

Prof. DEWAR: In proposing this motion, I would like to say that it is surely a strange thing for a Council such as this to have such an aversion to accepting money which will be given practically voluntarily by the profession, and that nevertheless we should have the power to compel members who are not able to pay to the funds of the College.

Mr. GARNETT: No one suggests that.

Prof. DEWAR: You are all suggesting it.

The PRESIDENT: Prof. Dewar is simply speaking for himself.

Mr. GARNETT: That is contrary to all that is in the Bill.

Prof. DEWAR: I move: "That the members of Council agree to give each a certain sum as a subscription to the funds of the College as an example to the profession, and that a general appeal for subscriptions be made to the whole of the members."

Mr. CARTER: I second that.

Mr. TRIGGER: I want to know before that is put to the meeting what is the sum suggested.

Prof. DEWAR: "A certain sum."

Sir JOHN M'FADYEN: I suggest that the prefix "un" should be inserted before "certain." (Laughter.)

Mr. TRIGGER: I want to know what sum Prof. Dewar suggests.

Prof. DEWAR: It is for the Council to suggest it. What do you suggest?

The PRESIDENT: I can only take the resolution as it is given to me, the other question can be settled afterwards.

The resolution was then put and lost, only the mover and seconder, Prof. Dewar and Mr. Carter, voting in its favour.

Mr. BARRETT: Shall I be in order if I move another amendment now?

The PRESIDENT: No. It has been voted upon, and no amendment can be moved to a resolution that has been already voted upon.

Mr. BARRETT: But I can move an amendment upon the original resolution?

The PRESIDENT: Yes, but not an amendment upon a thing that is already "squelched."

Mr. BARRETT: I beg to move "That an appeal be issued to the profession for funds, and that the Council be asked to head the list by offering subscriptions to it."

The PRESIDENT: I rule that that is covered already by the resolution that has been put.

Mr. ABSON: I should like to press for the names of the ayes and the noes to the resolution.

The PRESIDENT: Two voted for it, and the rest against.

The resolution for the reception and adoption of the report of the Finance Committee was then put and carried.

Mr. CARTER: Do I understand that this matter drops to the ground—that there is no appeal to be made to the profession?

The PRESIDENT: Precisely; that is the finding of the Council.

Major-Genl. THOMSON: May I say a word?

The PRESIDENT: The report of the Finance Committee is already passed.

Major-Genl. THOMSON: I was going to speak before it was actually passed. I was not aware that it had been received and adopted.

The PRESIDENT: Yes, it has been received and adopted.

REGISTRATION COMMITTEE.

The SECRETARY read the report of a meeting of the Registration Committee held on Thursday, January 11th, 1912, which stated that a letter (January 9th, 1912) was received from the London Master Carmen and Cartage Contractors' Association asking the assistance of the Council in dealing with cases of injustice arising through conflicting evidence of veterinary surgeons in prosecutions for alleged cruelty to horses, and it was resolved that the Secretary be instructed to reply, stating that while the Committee are to a considerable extent in sympathy with the views expressed, they regret they are not in a position to take any action in the matter, but that if the Association could supply details of any particular case in which injustice appeared to have been done, the Council would take such action as was legally possible to them.

In reply to another letter from a practitioner, the Solicitor was instructed to prosecute an advertiser if suitable evidence could be obtained.

The Committee proceeded to deal with 14 cases, in one of which a member appeared to answer a charge of advertising by means of a circular and a notice in *The Forthound*. Letters of explanations were read, and the Committee resolved: (a) that this Committee expresses its feeling of regret that circulars bearing Mr. Garside's name were issued; (b) that Mr. Garside's statement that they were published without his knowledge be accepted, his letter being accepted as an undertaking that the offence will not be repeated.

In another case it was resolved that a member be called upon to appear at the next meeting to show cause why his name should not be removed from the Register. The Solicitor reported prosecution and conviction

in the case of G. C. Hill, the defendant being fined with costs.

The Solicitor and Secretary were instructed as to the course of action to be taken in the remaining cases.

Restorations.—An application was received for the restoration of the name of Mr. G. H. Golding to the Register, the name having been removed under Section 5, Sub-section (4) of the Veterinary Surgeons Act, and it was resolved that the name of Mr. G. H. Golding be restored to the Register of Veterinary Surgeons.

On the motion of Major General Thomson, seconded by Mr. Roberts, the report was received and adopted; and on the motion of Mr. Mulvey, seconded by Major General Thomson, authority was given for the Seal of the College to be affixed to the Orders for prosecution mentioned in the report.

EXAMINATION COMMITTEE.

The SECRETARY read the following Report of a meeting of the Examination Committee held on Thursday, 11th January 1912:

Correspondence.—(a) Letters were received from the Examiners in Surgery, Class D, in connection with the Oral Examination in Liverpool in July, 1911, which were considered satisfactory.

(b) The Secretary reported the receipt of a letter from Dr. Noel Paton stating that he could not act as Examiner in Histology and Physiology, Class B, in December, 1911, but that the President had made arrangements for Prof. W. H. Thompson to act in his stead.

Reports on December Examinations.—The Reports of the Delegates, Chairmen of the Board of Examiners, and the Local Secretaries were read and considered.

It was resolved that the Secretary be instructed to forward letter of thanks in cases where rooms had been lent free of charge, and also where animals had been lent to the College for the purpose of Examinations.

Educational Certificates.—Educational Certificates numbered 1193 to 1249 were submitted and approved.

Schedule II.—The revision of Schedule II was considered, and it was resolved:

(a) That a Sub-Committee consisting of Dr. Bradley, Mr. Hobday, Prof. McCall, Sir John M'Fadyean, Prof. Mettam, Mr. Mulvey, Prof. Shave, Messrs. Sumner, Villar, be appointed to consider the syllabus in the Schedule and to report to this Committee at its next meeting.

(b) That the Secretary be instructed to obtain copies of regulations of other bodies and to submit them to the first meeting of the Sub-Committee to be held at 11 a.m. on Thursday, April 11th.

Jubilee Memorial and Bursary Examination.—It was resolved that the Examination for the Jubilee Memorial and Bursary Prize be held in the last week in August or the first in September, 1912.

Walley Memorial Examination.—The report of the Examiners on the Walley Memorial Prize was considered. The report showed that the following two students were bracketed equal first:—

P. R. Viljoen, 221½ marks. J. J. Cosgrove, 221½ marks. It was resolved to recommend that the value of the Prize be divided between the two students.

On the motion of Mr. Lawson, seconded by Prof. McCall, the Report was received and adopted.

PARLIAMENTARY COMMITTEE.

Mr. GARNETT read the following Report of a meeting of the Parliamentary Committee held on December 14th, 1911:—

Coal Mines Bill.—(a) The Chairman reported that it had been found necessary hurriedly to call together a deputation to the Home Office in connection with the inspection of animals in the Coal Mines Bill. These clauses had been inserted during the passage of the Bill through Committee, and had not been brought to his

notice until the Bill was at the Report Stage. In consultation with the President a deputation had been arranged consisting of the Chairman of the Parliamentary Committee, together with Messrs. W. Hunting, W. Woods, H. Peele, G. Elphick, the Solicitor and Secretary, who attended at the Home Office on November 30th, and were received by the Chief Inspector of Mines.

The Deputation represented that the fit persons to be appointed under Section 109, Sub-section 3 of the Bill, as special inspectors for the purpose of examining into the care and treatment of horses and other animals in mines, should be properly qualified Veterinary Surgeons, as had been recommended in Section 10 of the Third Report of the Royal Commission on Mines.

The Deputation claimed further that in paragraph I of the Third Schedule of the Bill providing for the testing of horses for glanders, it should be laid down that the persons to be appointed to perform this test should be duly qualified Veterinary Surgeons.

(b) The Solicitor reported to the Committee the further proceedings in Parliament and stated that a promise had been made on behalf of the Government that in the appointment of the special inspectors under Clause 109 the claims of Veterinary Surgeons should be considered.

Schedule III, paragraph 1, had been amended as follows:—

"No horse shall be taken underground until it is four years old and until it has been tested by a duly qualified Veterinary Surgeon in the prescribed manner, and certified to be free from glanders."

(c) It was resolved that in the opinion of this Committee it is in the public interest that the inspectors to be appointed under Clause 109 should not be laymen, but duly qualified Veterinary Surgeons, and the Solicitor was instructed to make arrangements for a Deputation to be received at the Home Office in order to represent the views of the Council as to the regulations to be drawn up for carrying out the provisions of the Act.

Motor and Petrol Taxes.—It was reported that an amendment had been put down on December 12th, 1911, by Mr. Sanderson, M.P. to Part 1, (4) of the Fifth Schedule to the Finance Act, to extend the allowances in respect of duty on motor spirits to Veterinary Surgeons, and a similar amendment to Section 86, Sub-section 4 of the Finance Act, with regard to motor duties. These amendments were, however, not successful.

Sale of Alcohol.—It was reported that the following amendment to the Finance Act had been moved in Parliament by Mr. Glyn Jones, M.P., and accepted:—

"Any manufacturing or wholesale chemist and druggist who requires a license for the purposes only of selling rectified spirits of not less than 43 degrees above proof for chemical purposes to duly qualified medical practitioners or duly registered Pharmaceutical chemists or chemists and druggists, or persons requiring the spirits for scientific purposes in any laboratory, and undertakes not to sell spirits otherwise than for those purposes, and to those persons, may obtain a license on payment of a reduced duty of ten guineas."

The Solicitor reported that a petition from the Council praying that the words "or Veterinary Surgeons" should be inserted after the words "Chemists and Druggists" in the above amendment had been laid on the table in the House of Commons, and that an amendment to that effect had been proposed in the House by Mr. Sandys, M.P., without success. The words in italics had, however, been inserted by Mr. Glyn Jones, and they would, to a large extent, meet the requirements of veterinary surgeons.

Parasitic Mange Order, 1911.—The Secretary read a letter from the Board of Agriculture dated Nov. 24, 1911, enclosing a copy of the Parasitic Mange Order for 1911.

It was resolved that Section 3 of the Order be reprinted in the Register of Veterinary Surgeons, together

with a copy of the Animals (Notification of Disease) Order of 1910.

General Purposes. Repairs. The Secretary reported repairs to the College buildings which had become urgently necessary, and the action he had taken was approved.

Mr. GARNETT read the following report of a meeting of the Parliamentary and General Purposes Committee held on Thursday, Jan. 11th, 1912:

Correspondence. (a) A letter was received from the Royal Sanitary Institute with regard to the appointment of a delegate at the Congress at York in July, 1912. And it was resolved that no action be taken.

(b) The Secretary reported the receipt of an Act to regulate the practice of veterinary surgery in Western Australia. And it was resolved that the matter be referred to the Melbourne University Degree Committee.

Coal Mines Act.—The Solicitor reported that he had been informed that regulations dealing with the inspection of animals were likely to be drawn up in the near future under the Coal Mines Act, and that a deputation from the College would be received if necessary.

It was resolved that the President, Sir John McFadyen, Messrs. Garnett and Mulvey be appointed a deputation to wait on the Home Office in connection with the regulations for the inspection of animals in mines.

Bills passed into law. The Chairman reported that in addition to the Coal Mines Bill, the Public Health (Ireland) Bill, 1911, had been passed into law, dealing with the making of bye-laws for the inspection of meat. And it was resolved that the President of the College be requested to watch the matter in the interest of the profession.

Private Bills.—The following Private Bills were submitted and considered:—Kingston-upon-Hull Corporation, Keighley Corporation, Sheffield Corporation, Shipley Urban District Council, Swansea Corporation, Tavistock Urban District Council.

It was resolved that with regard to the Swansea Corporation Bill, the Secretary be instructed to write pointing out that in Clause 106 the words "or of the medical officer" should be deleted.

Patent Medicines.—It was reported that a Parliament Select Committee was about to be appointed to inquire into the question of patent medicines.

And it was resolved that an endeavour should be made to obtain a representation on the Committee, and that the matter be left in the hands of the President with power to act.

Mr. GARNETT: I should like to say, in proposing that those reports be received and adopted, that there has been a considerable amount of work thrown upon Mr. Thatcher, our solicitor, in carrying out the business that has been entailed in regard to the Coal Mines Bill and the Finance Act during the past Session of Parliament, and I feel that it is only expressing the desire of the Parliamentary Committee that Mr. Thatcher should be specially thanked for his assistance in Parliament, sometimes night after night without any purpose, sometimes for a very great purpose, on behalf of this Council. (Hear, hear.) Without him, situated as we are, we could not possibly have carried into effect any of the provisions that we have been able to gain in either of these Acts. (Cheers.) I have very great pleasure in moving the adoption of the reports of the Committee.

Major Genl. THOMSON: I second that.

Prof. DEWAR: You said that a deputation was going to be received in connection with the preparation of the bye-laws under the Coal Mines Bill, if it was necessary. Is it the Home Office that is going to consider whether it is necessary that this Council should send a deputation?

Mr. GARNETT: At the present time I think it is perfectly satisfactory, and that we will be called upon to give an expression of opinion before any regulations are framed under the Coal Mines Bill. (Hear, hear.)

Mr. BARRETT: May I say one word in appreciation of the services which Mr. Thatcher has rendered in regard to these matters? I do not know if he will get any remuneration or not, but I know from my personal knowledge that he has attended the House of Commons on many occasions, and has devoted very much time and attention to our business there. I should, therefore, like very much to support what Mr. Garnett has said with regard to him. If he would move I would certainly second that the Council pass a vote of thanks to Mr. Thatcher for his services, which have been very onerous and very trying indeed. (Hear, hear.)

Mr. MULVEY: I should like to support the remarks made by Mr. Garnett. From time to time it is my unfortunate duty to criticise the accounts, but I should like to say that, having considered the accounts that have been sent in to this Council for the work that Mr. Thatcher has done, I am decidedly of opinion that his charges have been most moderate in every way.—(Cheers.)

Mr. LLOYD: I would like to ask one question from the Chairman of the Parliamentary Committee. Can he tell me what body in Ireland is going to draw up the Rules with regard to the inspection of meat? Is it left to the Local Government Board?

The PRESIDENT: Yes, the Local Government Board. Before putting the motion that the reports of the Parliamentary Committee be adopted, I should like also to give my voice in support of the words that have already fallen from the Chairman of the Parliamentary Committee and other members of that Committee. Mr. Thatcher has devoted a considerable amount of time to the business of this College, and, as I know, he has put in many hours at Westminster looking after the interests of the profession. I am sure that no remuneration that we could offer would indicate to Mr. Thatcher how much we appreciate what he has done. The other speakers have voiced their feelings very clearly, and I am sure they have voiced the feelings of the whole Committee, but I would like it also to go forth that I personally appreciate very much indeed what Mr. Thatcher has done for the profession. I will not put it to you by way of a formal vote, for I take it that you will all give Mr. Thatcher a vote of thanks by acclamation for the great trouble he has taken, and for the successful work he has done for us.

The vote of thanks was carried by acclamation.

Mr. THATCHER, who was received with cheers on rising to reply, said: Mr. President and gentlemen, I thank you very much indeed for what you have said. It was suggested that I had not received sufficient or adequate remuneration, but I assure you that the thanks of you gentlemen assembled round this table in this way is more than sufficient reward to me for what I have done. (Cheers.)

The motion for the adoption of the reports of the Parliamentary Committee was then carried unanimously.

PUBLICATION COMMITTEE.

The SECRETARY read the following report of a meeting of the Publication Committee held on Friday, January 12th, 1912:

Register 1911.—The Secretary submitted a statement of accounts in connection with the printing and sale of the Register for 1911, which was approved.

Register 1912. The Secretary submitted copies of advertisements to be inserted in the new edition of the Register, which he was authorised to accept.

On the motion of Mr. Abson, seconded by Mr. Bannham, the report was unanimously adopted.

MELBOURNE UNIVERSITY DEGREE COMMITTEE.

The SECRETARY read the following report of a meeting of the Melbourne University Degree Committee held on the 12th January, 1912:

St. Vincent Ordinance. An Ordinance to make provision for the registration of veterinary surgeons for the Island of St. Vincent, was received from the Secretary of State for the Colonies.

And it was resolved that the communication be acknowledged with thanks, the document to be filed in the College archives.

Western Australia Veterinary Act, 1911. A copy of an Act to regulate the practice of veterinary surgery in Western Australia was received.

And it was resolved that the communication be acknowledged with thanks, the document to be filed in the College archives.

On the motion of Mr. Barrett, seconded by Sir John McFadyean, the report was unanimously adopted.

WILLIAMS MEMORIAL PRIZE AWARD.

The SECRETARY announced that Messrs. Woodhouse and Wilkinson, chartered accountants, certified that the following was a correct statement of the marks obtained by the candidates in the Final Year Examinations during 1911 who obtained 60 or more marks in the subjects of Veterinary Medicine and Hygiene:

London, July, 1911.	J. T. Edwards	63	66	--	129
" " "	G. F. Steevenson	61	60		121
Liverpool " "	S. K. Jones	60	60		120
London, Dec. "	C. Holland	60	60		120

The PRESIDENT: Gentlemen, you have heard the report of the accountants as regards the Williams Memorial Prize. Mr. Edwards apparently has gained the largest number of marks in the professional final examinations. Will someone kindly move that the prize, which is worth £9, be awarded to Mr. Edwards?

Sir JOHN McFADYEAN: I have pleasure in moving that.

Major-Genl. THOMSON: I have much pleasure in seconding that.

It was unanimously resolved that Mr. J. T. Edwards should be the Williams Memorial Prizeman for 1911.

FELLOWSHIP EXAMINATION.

The SECRETARY reported that an examination for the Fellowship Diploma was held on December 2nd, 1911, when four candidates attended, and the following gentlemen passed the examination:

Messrs. A. F. CASTLE, FRANCIS J. DUNNING, and R. L. PHILLIPS.

PLACE OF ANNUAL GENERAL MEETING.

Mr. TRIGGER: I beg to move that the annual general meeting be held in London as usual.

Sir JOHN McFADYEAN: I beg to second that.

Mr. MULVEY: I am going to move an amendment. Our President, as is well known, lives in Ireland, and is the Principal of the College there. I think that as a compliment to him we ought this year, at all events, to change our place of meeting. I therefore move that this year the annual meeting be held in Dublin. (Cheers).

Mr. TRIGGER: I have no feeling in regard to the matter at all. I simply moved my motion in the ordinary course, and I have pleasure in withdrawing it.

Mr. ABSON: I have very great pleasure in seconding Mr. Mulvey's motion.

Sir JOHN McFADYEAN: I approve of the withdrawal of Mr. Trigger's resolution, which I unthinkingly seconded.

It was unanimously agreed that the annual general meeting for the ensuing year should be held in Dublin.

The PRESIDENT: Gentlemen, I thank you very much indeed for the compliment that you have paid me by deciding that the annual meeting shall be held in Dublin, and I am sure it is a compliment that will be appreciated by all the members of the profession residing in Ireland. I hope that we shall be able to have a very successful meeting which will redound to the credit, and will further the interests, of the profession at large. (Cheers).

NOTICE OF ALTERATION OF BYE-LAWS.

Sir JOHN McFADYEAN: At the last meeting of Council the Chairman of the Examination Committee gave notice of certain alterations in our bye laws. This was merely to give effect to the recommendations made by a Special Committee to which the consideration of the bye-laws had been remitted. The notice of the intended alterations has, I believe, been suspended for the necessary three months, but Mr. Villar, the Chairman of the Examination Committee, who is unfortunately unable to be present to-day owing to an unforeseen and unavoidable engagement, has asked me to say that he does not desire to move that these alterations be now passed, because in spite of the very careful consideration which the bye-laws received, an alteration which really appears to be necessary, or at least highly advisable, has been overlooked. It is in connection with Bye-law 62, which according to notice suspended on the board reads thus: "Should a candidate conduct himself disrespectfully or otherwise improperly at any meeting of the Court of Examiners, the Chairman of the Class is empowered to stay the examination of such candidate, and report the transaction to the Council, who shall deal with the offender." Unfortunately the fact had been overlooked for a good many years that the Chairman of the class is, in ordinary circumstances, not present at the examinations, and therefore was unable to act as directed or empowered by the bye law. It is therefore proposed to alter Bye law 62 so that it shall read as follows: "Should a candidate conduct himself disrespectfully or otherwise improperly at any examination, the Chairman of the Class or the delegate or officer of the Council is empowered to stay the examination," etc. I therefore, on behalf of Mr. Villar, beg to give fresh notice of the intention to move these alterations of the bye-laws three months hence. I desire also, sir, to give notice of my intention to move at the next meeting of Council an addition to Schedule 1. I propose to move that the Matriculation Examination of the University of Bristol be added to the Schedule. It is a new examination. This is perhaps hardly the time to say so, but we have ascertained that it is an examination already recognised by the General Medical Council.

Mr. MULVEY: I suppose this is not the time at which to discuss these amendments, but when they are open for discussion at the end of three months I shall have something to say.

The PRESIDENT: Are there any other notices of motion?

Prof. DEWAR: I would like to ask this question, Mr. President. Supposing after these alterations have been suspended for three months an amendment is proposed to any of these alterations that have been put up, can that amendment be drafted on to the motion and agreed upon?

The PRESIDENT: No, it would have to be put up again.

The alterations of which Sir John McFadyean gave notice on behalf of the Chairman of the Examination Committee are as follows:

56. A Session shall be a period of not less than thirty weeks, exclusive of the recognised holidays of the Institution at which the Student shall have studied.

57. The Examination for the Diploma of Membership shall be held in each city in which there is situated an affiliated Veterinary School twice during each year as follows : In England and Ireland in July and December, and in Scotland in May and December. At the Quarterly meeting of Council held in July in each year the Council shall fix the dates of the Membership Examinations to be held during the following December, May, and July.

58. An Examination fee of five pounds shall be paid for each Examination, and successful candidates for the Diploma shall pay a further fee of one pound for registration.

59. Should a Student fail in any Examination he shall pay a further fee of three guineas for each re-examination.

60. No candidate shall be eligible for any examination unless the Examination fee be paid at least seven days prior to such Examination.

61. Any candidate who through misstatement, error, or false certificate shall seek, or be led, to apply for any Examination, shall be prohibited from undergoing that Examination, or if he has undergone it, shall not be permitted to enjoy the advantages to be derived therefrom, and shall be declared disqualified for such Examination for such a period as the Council shall see fit.

62. Should a candidate conduct himself disrespectfully or otherwise improperly at any examination, the Chairman of the Class, or the delegate or officer of the Council, is empowered to stay the Examination of such candidate, and report the transaction to the Council, who shall deal with the offender.

63. No rejected Student shall be eligible for re-examination unless he produces satisfactory evidence that he has attended a full term of ten weeks at a Veterinary College between the dates of rejection and re-examination.

64. If a candidate who has been rejected at a Final Examination fails to present himself for re-examination within one year (except in case of illness or other cause satisfactorily certified), he shall be precluded from further re-examination.

65. Candidates shall be tested in each subject by a written Examination where not otherwise specified, and an oral Examination on the living or other specimens. Written papers to consist of six questions, but only four to be attempted, except in Class D, when eight questions shall be set, and six attempted.

66. The written Examination shall commence at 10 a.m. on the days to be fixed by the Council. Each Examiner shall set three questions (except in Class D, when each Examiner shall set four questions), the answers to which he shall read, mark, and return to the Secretary as soon as possible. The time allowed for each subject is specified in the scheme set out in By-Law No. 67. Answers shall be written on one side of the paper only, and each question answered on a separate sheet. Each candidate shall be given an examination number and each paper shall be signed with such number only, and not with the name of the candidate. Passage of papers, references to books or documents, talking or copying shall render the Candidate liable to immediate dismissal from the examination room, at the discretion of the representative or representatives of the Council, present.

67. The subjects for each Examination, and the time to be devoted to each subject, shall be as follows :

EXAMINATION A.

1. Anatomy of Domesticated Animals : — Bones, Ligaments, Joints, (written, 2 hours ; oral, 15 minutes).

2. Chemistry and Elementary Physics (written, 2 hours ; oral, 15 minutes).

3. Biology : —Elementary Zoology and Botany (written, 2 hours ; oral, 15 minutes).

EXAMINATION B.

1. Anatomy of Domesticated Animals (written, 2 hours ; oral, 20 minutes).

2. Histology and Physiology (written, 2 hours ; oral, 20 minutes).

3. Stable Management and Manipulation of Domesticated Animals and Principles of Shoeing (oral only, 30 minutes).

EXAMINATION C.

1. Morbid Anatomy, Pathology, and Bacteriology (written, 2 hours ; oral, 15 minutes).

2. Materia Medica, Practical Pharmacy, Therapeutics, and Toxicology (written, 2 hours ; oral, 30 minutes).*

3. Veterinary Hygiene and Dietetics (written, 2 hours ; oral, 15 minutes).

EXAMINATION D.

1. Principles and Practice of Veterinary Medicine and Meat Inspection (written, 3 hours ; oral, 1 hour).

2. Principles and Practice of Veterinary Surgery and Obstetrics (written, 3 hours ; oral, 1 hour).

Examiners.

68. The Council shall appoint a sufficient number of persons to constitute the Court of Examiners, and shall from time to time fill any vacancies which may occur.

69. There shall not be less than two Examiners to each subject.

70. An Examiner in any one class, shall not examine in any other, in the same set of Examinations.

71. Each candidate for the office of Examiner shall, at least fourteen days before the date of election, intimate in writing to the Secretary (either by himself, or with his consent, by a Member of the Royal College of Veterinary Surgeons), his desire to be appointed, and submit with his application a statement of his qualifications, and a copy of any testimonials he may possess as to his especial fitness for the position he seeks. The name and qualifications of each candidate shall be suspended on the notice board at the College, as and when received, and appear on the circular convening the Meeting at which the Examiners are to be appointed. Each Examiner shall be elected for such period not exceeding three years as the Council may think fit. Each Examiner shall be eligible for re-election. Any Examiner shall be removed by the vote of two-thirds of the Members present at any meeting of the Council, to be confirmed by a Special Meeting called for the purpose.

72. Every member of the Court shall be entitled to such fees as shall from time to time be fixed by the Council.

73. Each Class of the Court of Examiners shall elect a chairman from amongst its members. In the event of any Examiner being unable to attend at any centre, the President, or, in his absence, the Chairman of the Examination Committee or failing these the Chairman of the Class in which the vacancy occurs, shall have power to select a substitute to act in his stead at each centre at which the Examination is to be held.

74. Local Secretaries to the Court of Examiners shall be appointed by the Council, and shall not be eligible to act as Examiners. Such Secretaries, acting on the instructions of the Secretary, R.C.V.S., shall be responsible for the arrangements of, and provision of specimens for, the Examinations at each centre in England, Scotland and Ireland respectively.

75. The marks to be used by the Examiners in the record of Examinations shall be indicated by numbers. One hundred marks shall be the maximum in each sub-

* At the Oral Examination two students shall present themselves at the same time, and shall be examined for fifteen minutes by each Examiner.

ject. The written and oral sections of the Examination shall be taken conjointly for the purpose of estimating the result of each Examination. An aggregate in the written and oral portions of forty-five per cent. in each subject shall qualify for a Pass. Sixty per cent. in each subject shall qualify for Second Class Honours, and seventy-five per cent. in each subject shall qualify for First Class Honours.

76. Each Student shall be examined in each subject of his Class, and at the conclusion of the Examination the Examiners shall confer, and the sense of the whole shall be taken as to the qualifications of the Students.

77. Should the result of the Examination of any Candidate appear doubtful to the Examiners, they may re-examine him. The award of marks made by the Examiners shall be final.

78. The Local Secretaries to the Court of Examiners shall immediately on the conclusion of the Examination notify in writing to the Council the names of Students who have passed the Examination and specify those who have gained honours.

79. A report of each Examination shall be drawn up and signed by the Chairman of each Class and shall be transmitted to the Council, stating the number of successful candidates, and the general standard attained in each subject, and referring to any other matters which it is desirable should be notified to the Council.

80. Copies of Examination record sheets shall be supplied to the Principals of each school.

81. One or more Members of Council shall be delegated to attend each Professional Examination. The travelling expenses of the delegates, together with an allowance of one guinea per night spent away from home on the business of the Examinations shall be defrayed out of the College funds.

82. Subject to the preceding Bye-laws as above, the Chairman of each class of the Examiners may refuse admission, during Examination, to any person whose presence may be deemed objectionable.

83. The President, or in his absence the senior Vice-President, may direct a Special Court of Examiners to be holden on any emergency.

Admission to Membership.

84. No Student shall be entitled to receive the Diploma, or have his name entered on the Register of the Royal College, until he has completed his twenty-first year, but he may present himself for his Final Examination, provided he would complete his twenty-first year before the date of the next Examination to be held at the centre where his course of studies has been pursued.

OTHER BUSINESS.

MR. STOCKMAN: At a meeting of the Organising Committee of the International Veterinary Congress, 1914, to be held in London, it was resolved yesterday that this Council should be asked to grant 10 Red Lion Square as the Official Office of the Committee. I would now like to propose that for the acceptance of the Council.

MR. ROBERTS: I second that, sir.

THE PRESIDENT: I am sure the Council will be only too willing to do what they can to assist the efforts of the Committee to make the Tenth International Congress a great success. I therefore formally put to the Council that permission be given to the Committee of the Tenth International Congress to utilise the offices of the College as their headquarters.

The resolution was carried unanimously.

THE PRESIDENT: Mr. Thatcher has an announcement to make which he thinks will be of interest to you.

MR. THATCHER: It is a matter of general interest to the Council. The question of the right of members to use armorial bearings of the College without extra payment was decided this morning by the Divisional Court,

and the opinion of the Judges was unanimous that if veterinary surgeons wished to do that they must pay a separate duty.

VOTE OF THANKS TO THE PRESIDENT.

On the motion of Prof. McCall, seconded by Prof. Dewar, a hearty vote of thanks was accorded to the President for his conduct in the chair, which the President briefly acknowledged, and the meeting terminated.

Use of the College Arms.

LONDON COUNTY COUNCIL v KIRK.—APPEAL.

The Appeal of the London County Council from the decision of Mr. Curtis Bennett, the magistrate at Bow Street, came before the Divisional Court in the King's Bench of the High Court of Justice on Friday morning, 12th January, 1912. The judges were the Lord Chief Justice, Mr. Justice Pickford and Mr. Justice Avory. Mr. A. H. Bodkin, instructed by the Solicitor to the London County Council appeared as counsel for the Appellants, and Mr. F. T. Barrington Ward, (instructed by Mr. Philip Conway) appeared as counsel on behalf of the respondent.

Mr. Bodkin, in opening the case for the appellants said the case was originally dismissed by the learned magistrate at Bow Street, and the appellants thereupon applied for a special case. The question involved was whether a gentleman who was a member of a Collegiate or Corporate body was entitled, for his own private business purposes, to use the armorial bearings of that body on his notepaper or in other ways without taking out a licence under the Revenue Act of 1869. The learned magistrate seemed to have come to the conclusion that Mr. Kirk was not using the armorial bearings in the sense given to that word in the statute, and dismissed the summons. The information was laid under Section 17 of the Revenue Act, 1869, which made it an offence for any person to wear or use any armorial bearings without having a proper licence under that Act. The Section which provided the licence duty, which was a guinea, was Section 18 of the same Statute: For armorial bearings. If such armorial bearings shall be painted, marked, or affixed on or to any carriage—£2 2 0. If such armorial bearing shall not be so painted, marked or affixed, but shall be otherwise worn or used—£1 1 0. The only exemption in the Statute to the necessity of taking out a licence was provided by Section 19, Sub-section 1, which provided that "It shall not be necessary for any member of the Royal Family to make any declaration or to take out any licence under this Act, nor shall it be necessary for the sheriff of any county, or mayor or other officer in any corporation or royal burgh serving an annual office therein, to take out a licence for any servants, carriages, or horses employed or kept by him for the purposes of his office during his year of service, nor for any person who shall by right of office wear or use any of the arms or insignia of any member of the Royal Family, or of any corporation or royal burgh, to take out a licence in respect of the use of such arms or insignia." "Corporation" in that sense he submitted meant the kind of Corporation which was mentioned earlier in the Clause.

The Lord Chief Justice said the proceedings in the present case were not against a Royal College, but against a man.

Mr. Bodkin replied in the affirmative. Proceeding, he said that under the same section, Sub-Clause 13, armorial bearings were defined as follows: "Armorial bearings" means and includes any armorial bearing, crest, or ensign, by whatever name the same shall be called, and whether such armorial bearing, crest or ensign shall be registered in the College of Arms or not."

The Lord Chief Justice said the exhibit in the case, a letter written by Mr. Kirk on the note-paper in question had on it the arms of the Royal College, but no reference to the Royal College, and his own name appeared in a kind of garter, "William Kirk, Veterinary Surgeon". There was nothing to shew those were not his own arms.

Mr. Bodkin replied that that was so, and that he did not know the general public would be acquainted with the proper arms.

The Lord Chief Justice said it seemed to have been suggested that the placing of the arms on the notepaper would tell people that he was a member of the Royal College. How it was going to do that he did not know.

Mr. Bodkin said he did not think the words *vis unita fortior* would indicate that to the general public.

The Lord Chief Justice: What does that mean? I think you ought to tell us, Mr. Bodkin. (Laughter.)

Mr. Bodkin: I think my friend, Mr. Barrington Ward, will probably meet that point. (Laughter.) Mr. Bodkin proceeded to read the following facts which were set out in the case stated by the Magistrate:

"The following facts were proved in evidence or admitted by the parties before me:—(a) The respondent practises as a member of the Royal College of Veterinary Surgeons at 9, Bailey Street, W.C. (b) In connection with and for the purposes of the said business and practice he used, and has used for many years past, certain headed notepaper, and was using the said notepaper on the day alleged in the said information. (c) The sheet of notepaper in respect of which the said information was laid is annexed to this case and marked "H.C.B.I." It is the respondents ordinary business (not private) notepaper. (d) The device on "H.C.B.I." consists, in the centre, of the proper arms of the Royal College of Veterinary Surgeons stamped in black on a description of shield stamped in relief upon the said paper, the whole being enclosed within an ornamental circular device bearing the words "William Kirk, Veterinary Surgeon." Apart from such device there is nothing on the said notepaper to indicate that the respondent is a member of the Royal College of Veterinary Surgeons. (e) No licence in pursuance of Section 18 of the Revenue Act 1869 (32 and 33 Vic. c. 14), has ever been taken out by the respondent, authorising him to wear or use the said armorial bearings. (f) The Royal College of Veterinary Surgeons take out annually, under the said Statute, a licence to use and wear the said armorial bearings. There are about 3,000 veterinary surgeons in England who are members of the said Royal College of Veterinary Surgeons."

The Lord Chief Justice: If this decision is right, all those gentlemen can use that same device and can say they are not liable to pay that licence?

Mr. Bodkin: That is the contention. "(g) The respondent uses, and has used the said headed business notepaper as an indication that he is a duly qualified veterinary surgeon. It was contended before me by the respondent that it was not necessary for him to take out any licence under the Revenue Act 1869 in respect of the said armorial bearings appearing upon the said business notepaper; that he being a member of the said Royal College of Veterinary Surgeons was entitled to use the armorial bearings thereof as indicating his membership without taking out any licence in respect of such user for such purpose; that he was not "using" the said "armorial bearings" within the meaning of the said Revenue Act 1869, as he used them only for the purpose of giving notice to the public that he was a duly qualified veterinary surgeon and a member of the said College; and that the said Statute only rendered a licence for armorial bearings necessary when a person used his own armorial bearings."

It was contended before me on the part of the appellants that the said device upon the respondent's said

business notepaper amount to "armorial bearings" and were in fact the true armorial bearings of the said College: that although the said College took out a licence in respect of its own user of such armorial bearings as a Corporate Body, that fact did not justify the use of such armorial bearings by members of the said College for their own business or other purposes without proper licenses; that the definition in Section 19, Sub-section 13, of the Revenue Act 1869 included the said armorial bearings; that by reason of the character of the device on the said notepaper as shown on "H.C.B.I." the respondent must be taken to be "using" within the meaning of the said Statute the said "armorial bearings"; and as he used them for his own benefit in his own business to indicate his position in the profession of veterinary surgeon, he was "using" such armorial bearings within the meaning of the said Statute; and that it was not necessary in order to render a licence necessary under the Revenue Act 1869, that the armorial bearings used by a person required to take out a licence should be his own armorial bearings, or armorial bearings properly or heraldically so called, but that a person using a device amounting to armorial bearings as defined under the said Act, is required to take out a licence.

I was of opinion that the respondent was not liable to take out a licence to use armorial bearings under the said Revenue Act 1869 under the circumstances above set forth; that he was only using the said device upon his said business notepaper as an indication that he was a veterinary surgeon and a member of the College, and that for a member of the said Royal College of Veterinary Surgeons to use the recognised armorial bearings of such a Corporation to indicate his membership thereof was not "using" armorial bearings within the meaning of the said Revenue Act 1869, and I accordingly dismissed the said summons. The question for the opinion of this Honourable Court is: Whether I came to a correct determination in so dismissing the said information as above stated. If I was right in law in so dismissing the said information the said dismissal is to stand; if not, the case is to be remitted to me with the opinion of this Honourable Court thereon."

The Lord Chief Justice: I cannot understand at present why it is an indication that he was a veterinary surgeon.

Mr. Bodkin said he was in Court at the time the learned Magistrate decided the case, and heard the Magistrate say he had looked at Johnson's Dictionary for a definition of armorial bearing, and found it was "The Arms or Escutcheon of a family."

The Lord Chief Justice said that that was not the ground of the Magistrate's judgment. Had there been any cases decided about clubs?

Mr. Bodkin replied in the negative. The learned Magistrate in his judgment further mentioned the illustration of persons playing cricket or some other game, and wearing caps or garments bearing College arms, and asked whether that could possibly be said to be a user of armorial bearings which would necessitate cricketers or football players taking out a licence. He submitted those instances were entirely different from the present case.

The Lord Chief Justice said that the use of arms on notepaper was the commonest thing possible.

Mr. Justice Ivory stated that in his recollection every undergraduate used the arms of his College upon his notepaper and on letters which were written on purely private business.

Mr. Bodkin: But only at College, my lord.

Mr. Justice Ivory: Yes.

Mr. Bodkin: And that is the real distinction that I am venturing to draw. If the respondent was in such premises as the Royal College of Veterinary Surgeons possesses, and was using in that building for the purposes of the College the College notepaper, the licence

taken out by the Corporation would cover his user of that paper, but if he took that notepaper away.

The Lord Chief Justice : You need not go as far as taking the notepaper away, which might be an accident; but here this gentleman has put within his own name a crest, and there is nothing in the world to show it is not his own crest, and nothing to show it is the crest of the Royal College.

Mr. Bodkin : That is so, my lord.

The Lord Chief Justice : Why I ask that is that I constantly write on notepaper with the Arms both of Oxford and Cambridge upon it, and I thought I might be liable in other respects for the use of other arms. But you do not pay twice over. You can use any arms you like once you have paid, and that is why I asked whether a club case has ever come before the Courts.

Mr. Bodkin : As far as I can discover no club case has ever come before the Court.

The Lord Chief Justice : In the Benches of the Temple the barristers use the notepaper with the Arms of the Lamb and the Horse upon it.

Mr. Justice Avory : They do that in the Common Room.

Mr. Bodkin : Yes, but if a member of the Bar put a horse on the top of his notepaper he would have to pay the license duty, I submit.

The Lord Chief Justice : That would be this case !

Mr. Bodkin : Yes, because I should be using for my own purpose Arms which amount to Armorial Bearings within the Statute.

Mr. Justice Avory enquired whether there was any other exemption in the Statute except the one in Section 19.

Mr. Bodkin replied that that was the only exemption.

Mr. Justice Avory enquired if that was so why the Inland Revenue printed upon the yellow demand note that in the case of Armorial Bearings there was an exemption in the case of clubs and members of a society using the Armorial Bearings on the business of the society.

The Lord Chief Justice stated that he had never looked at such a yellow paper.

[One of the yellow papers in question was then handed up to his lordship who read the following statement from it : "Exemptions. Licences are not required from : 1. The Proprietors of Public Stage Carriages or of Hackney Carriages Licensed by Local Authority, in respect of any Armorial Bearings marked thereon, or on the harness used therewith. 2. Shopkeepers in respect of the use of Armorial Bearings or Devices solely as trade marks, and in the course of trade. 3. Any Officer or Member of a Club, or Society, using at the Club, or on the business of the Society, any Armorial Bearings for the use of which such Club, or Society, has taken out a licence." I am much relieved by that. I never read it before].

Mr. Justice Avory : This must be the result of some decision, or is it mere departmental law ?

Mr. Bodkin : It is the practice.

The Lord Chief Justice : Is there any settled case in regard to the clubs ?

Mr. Bodkin : No. This exemption 3 on the demand note refers to use at the club premises.

The Lord Chief Justice : It does not cover this case. It seems to go further than the Statute had authorised.

Mr. Bodkin : All members of a club are supposed to be in their own private house, and all have equal rights.

The Lord Chief Justice : Take the case of a cabbie using my harness with my crest upon it, or my carriage. What is the authority for letting him off ? Suppose I sell my carriage to you and you are very proud of the Arms on it, and use it. Can you do that ?

Mr. Bodkin : No, quite apart from the penalties of impersonation which might arise. (Laughter.)

The Lord Chief Justice : We really want to know how that exemption got there.

Mr. Justice Avory : The words which I think are important, if they have any authority, are "any member of a Society using on the business of the Society." That seems to create an exemption if the Arms of the College were used on the business of the College, but if there is no authority for it that does not apply.

Mr. Bodkin : There is no statutory authority for it. It is a reasonable interpretation, as I submit, of the Statute that if there is a licence at a place taken out by a corporate body which does not write itself, the members who are acting on behalf of that corporate body or under the immediate shelter of the licence would not be themselves obliged to take out a licence under this Statute ; but if a person independently of the purposes of the Society, or away from the premises which are sheltered by the licence, uses the Armorial Bearings for his own purpose, then he is bound to take out a licence. That is the practical view which the Inland Revenue have put on this Statute.

Mr. Bodkin, in conclusion, proceeded to quote two legal authorities in support of his contention that a person who used Armorial Bearings within the definition of the Statute was equally liable whether they were his own Arms or not.

Mr. Barrington Ward, in opening the case on behalf of the respondent, submitted that the decision of the learned Magistrate was right. There were, he contended, two quite distinct questions to be considered : one a mixed question of law and fact, namely, whether the particular emblem was an Armorial Bearing within the meaning of the Act, and secondly whether the defendant was using it within the meaning of the Statute. It might be a bold proposition, but he submitted that, in the circumstances of the case, they were not Armorial Bearings at all. He submitted, on the first point, that Magistrate had to ascertain as a question of fact what the particular device was.

The Lord Chief Justice : But he has not found them to be Armorial Bearings. What he has found is that he was using them to indicate he was a member of the College, but he was not using them within the Statute.

Mr. Barrington Ward : If I may say so with great submission, I do not think he has found anything very clearly at all. There is no specific finding anywhere, and I submit it is open to me to argue to-day that this device is really not an Armorial Bearing.

The Lord Chief Justice : The only reason I put that to you is that if it had been a finding of fact we might have been bound by it, but there is no finding of fact that they are not Armorial Bearings.

Mr. Barrington Ward : The region of fact is very narrow indeed : it almost at once becomes a question of law : because one only has to look at the note-paper and then read the definition and it is a question of law as to whether the one covers the other. Continuing, the learned counsel submitted that looking at the document and bearing in mind that it did not matter whether it was a man's own Arms or not, the magistrate had to ask himself what was the purport of the emblem. He submitted that was a question of fact, and that the magistrate had found on that part of the case that the purport of it was to indicate to the world at large that Mr. Kirk was a duly qualified veterinary surgeon.

The Lord Chief Justice enquired whether that exemption was contained in the Statute.

Mr. Barrington Ward submitted that it did not come within the terms of the Statute at all, because whatever was being used it was not an Armorial Bearing, because some limit must be put upon the definition.

The Lord Chief Justice asked what there was to show, looking at the note-paper, that the gentleman was a member of the College.

Mr. Barrington Ward submitted that it was not so

much a question of what was actually shown but what was in his mind at the time, what he was using it for. Was he using it for his own glorification, or was he using it as a warranty to the public that he was a duly qualified veterinary surgeon. The magistrate had found that all Mr. Kirk intended to do was not to glorify himself in any way but to hold himself out to the public, as the fact was, that he was a duly qualified veterinary surgeon.

Mr. Justice Avory enquired whether that was not a form of glorification.

Mr. Barrington Ward submitted not; it was simply a question of trade. In the absence of authority on the point he desired to submit one or two illustrations. He contended that the use of the Armorial Bearings in the present case was in the same category as the pole that a barber exhibited outside his shop to show that the man was a duly qualified competent barber.

The Lord Chief Justice: Those poles used to be used; they have nearly all disappeared now.

Mr. Barrington Ward: Then there is the Highlander outside the tobacconists' shops.

The Lord Chief Justice: And the pawnbroker with the three balls outside his shop. (Laughter).

Mr. Barrington Ward: Yes, and the pestle and mortar outside a chemist's shop. Take the case of the three balls. Suppose a man to indicate his business as a pawnbroker exhibits the three balls, those in some circumstances would be Armorial Bearings, but outside his shop obviously not; and I submit so long as he is carrying on the business of a pawnbroker and puts three balls up in the corner of his notepaper that those are not Armorial Bearings at all; they are merely a trade device indicating that he is a pawnbroker. I submit that Mr. Kirk is doing exactly the same thing. He is merely indicating to the public that he is a duly qualified veterinary surgeon.

The Lord Chief Justice: I do not want to press you, because it might seem unfair, but look at that notepaper, and assume I received it. He has not put M.R.C.V.S. upon it. What is there to tell a man that that is not his own crest?

Mr. Barrington Ward: I say quite frankly that there is nothing there to show it.

Mr. Justice Pickford: What is the little thing at the top. Is it a man on a horse?

Mr. Barrington Ward: I think it is a kind of centaur.

Mr. Justice Pickford: Will you tell me whether you say that is a crest or not?

Mr. Barrington Ward: I submit it is part of a crest. I do not think it is the full Arms of the College.

Mr. Justice Pickford: I am not speaking so much of the Arms. Would you call that little thing at the top a crest?

Mr. Barrington Ward: I think there is no doubt about it.

Mr. Justice Pickford: Then Armorial Bearings are defined to be "Any Armorial Bearings, Crest, or Ensign."

Mr. Barrington Ward, continuing his argument, quoted another instance which he said was probably an extreme one, in which if a man took a coin of the realm, pressed it on a piece of paper, and then used that paper the applicants would contend that he was liable to pay for the licence under the Act. He contended that there must be some limit to the generality of the words contained in Sub-section 13.

The Lord Chief Justice said the question was whether Mr. Kirk came within the exemptions.

Mr. Barrington Ward said he was in the difficulty that he could not bring himself within the only statutory exemption, because the words of the Section meant some sort of municipal Corporation, and even assuming that he could rely upon that Mr. Kirk could hardly be said to be using the Arms by right of office inasmuch

as he was a member. That being so unless he could bring himself altogether outside the words of the Act, *i.e.*, unless he could show they were not Armorial Bearings, and that he was not using them, it was very difficult to see under what ground of exemption he came. He submitted that the Magistrate, having gone into the matter and having ascertained that the real nature of the user of the emblem was simply as an indication to the public, their lordships should not interfere with the decision—that the question should be treated as a mixed question of law and fact, and in so far as it was a question of fact that the finding should be supported. With regard to the second point, whether the respondent was using Armorial Bearings within the Act, he submitted the word "using" must have some limit. "User" must mean user for some purpose. He submitted the distinction was, Was Mr. Kirk using it to mark himself off as an individual, or was he merely using it to show to the public that he was a member of a particular class? If the former, then of course he was within the Act; if the latter then he submitted he was not. He submitted that a person who used an emblem merely to show that he belonged to a particular class of persons, in accordance with the illustrations he had mentioned, could not be said to be using Armorial Bearings.

The Lord Chief Justice: I want to do justice to Mr. Kirk, but I cannot see how this notepaper can be any indication at all that he is a member of the Royal College of Veterinary Surgeons. One person in a thousand does not know what the Arms of the College are.

Mr. Barrington Ward: It is not a sort of question, my lord, that one can usefully argue at any great length, because it is more or less a question of impression. One looks at that notepaper, and either it is or it is not. All I can submit to your lordships is that by these various analogies that I have endeavoured to use there must be some limit on the word "use" in the Statute, and I submit the limitation must be the purpose for which the user takes place. Is it to distinguish the gentleman himself, or is it merely to mark him off as belonging to a particular class of persons? An undergraduate or a graduate at Oxford or Cambridge does not use his College Arms in any way to aggrandise himself; he uses them to show that he belongs to the Society.

The Lord Chief Justice: I thought I was rather aggrandising myself when I put the Arms of Trinity on the top of my writing paper. (Laughter).

Mr. Barrington Ward: The only aggrandisement would be in marking out yourself as being a Trinity man to other people. That, I submit, is different from marking oneself out to be a distinguished person because one happens to bear Arms which do not belong to you.

Mr. Justice Avory: If a man uses a Coronet he is representing himself to be a member of the House of Lords, but you say that is not for his own personal aggrandisement but only to represent he is a member of the House of Lords.

Mr. Barrington Ward: My lord, any argument, based upon that body is sometimes apt to be dangerous! (Laughter).

The Lord Chief Justice: Oh, you may say what you like, Mr. Ward, about the House of Lords. (Laughter)

Mr. Barrington Ward proceeded to argue that if their lordships found against the respondent, they should not mulct him in costs in view of the peculiar circumstances under which the dispute had arisen.

The Lord Chief Justice requested Mr. Barrington Ward to "wait and see" with regard to the question of costs, and without calling upon Mr. Bodkin to reply delivered the following judgment.

JUDGMENT.

The Lord Chief Justice: In my judgment the learned Magistrate, to whose opinion we always attach the

greatest weight, has gone wrong. He has thought that as the device was only being used on Mr. Kirk's notepaper as an indication that he is a veterinary surgeon and a member of the College, he was not within the Statute. We have the thing before us here, and it is a little difficult to understand how it can be thought it was an indication that he was a member of the Royal College of Veterinary Surgeons; all that we see is the crest. Of course if it does happen to go to a particular individual who knows the arms he may draw that conclusion, but it seems to me that that is much too narrow a view to take of it. We have got to deal with what the practical effect of it is. The practical effect is that Mr. Kirk has put upon his notepaper, with his own name as a veterinary surgeon there situated, Armorial bearings, and he uses that paper in the course of his business. Under those circumstances, in my opinion he comes under the words "Armorial bearings which are not upon a carriage, that is, so painted, marked or affixed, but shall be otherwise worn or used," and it seems to me that the common use of armorial bearings, one of the most common uses, is on notepaper, and he comes within those words.

Now is it within the exemption? It is agreed by Mr. Ward, who has argued every possible point, that there is no statutory exemption. Then it is said that we are to hold he does not use them at all because he, in his own mind, had the idea, in assuming that, or indicating that he was a member of the College. In my opinion that is not an exemption within the Statute; there is no authority of case law based upon the Statute, or construing the Statute, which affords any such exemption. It seems to me, therefore, this is a very plain case of use of armorial bearings without paying a licence.

On the case as stated, the exemptions on the yellow paper do not help Mr. Ward's client. He says that some case might have been made about the use of them which does not arise here; but one cannot help pointing out that these yellow paper notices have not any statutory authority, and if that may be supposed to be the practice of the Office, there is nothing in the practice so indicated that helps Mr. Ward's client in this case. I am not sure that those particular yellow paper exemptions are properly before us, but I have looked at them because they were referred to by my brother Avory, and Mr. Ward had them here ready for us. I think this case must go back to the Magistrate with a direction to convict.

Mr. Justice Pickford: I agree.

Mr. Justice Avory: I agree.

Mr. Bodkin: I ask that the appeal be allowed with costs. There has been a good deal of correspondence since the Magistrate's decision between the London County Council and the College, and the matters were pointed out to them as to how the legal position stood, but the College and Mr. Kirk went forward to get this decision. I submit that it is a matter in which costs should follow the event.

The Lord Chief Justice: I do not quite see why the costs should not follow the event. Have you anything to say that will move our souls to compassion?

Mr. Barrington Ward: I submit in a case of this sort, which is a test case, in which there is no authority one way or the other before, in a case where there has been a change in the method of collection of the revenue, and thereby a change in the practice, that there should be no costs. I have a letter here written as long ago as 1892 from the Inland Revenue Authorities saying that so long as the College paid the licence members might use the crest on their business paper with impunity.

Mr. Bodkin: In the College.

Mr. Barrington Ward: No, generally. I have the letter here, and if my learned friend likes I will read it. Mr. Kirk relied upon that.

The Lord Chief Justice: Who is it addressed to?

Mr. Barrington Ward: It was written by the Secretary of the Inland Revenue.

The Lord Chief Justice: We are really going into matters which are not before us. It is rather a long assumption to say that this particular individual relied on that letter.

Mr. Barrington Ward: I understand he actually made enquiries as to the matter, and that has been the practice of the Veterinary College since the date of the letter. I understand it came from the then Solicitor of the Inland Revenue and was addressed to the Solicitor of the College. May I read it?

The Lord Chief Justice: No, I do not think that is enough. We ought not to go into those letters. He has instructed you to fight the case on the merits, and not put it that he was misled or anything of that kind. He has persisted in the case; he defended before the magistrate and defends here. I think the appeal must be allowed with costs, with a direction to the magistrate to convict.

REVIEW.

FLEMING'S VETERINARY OBSTETRICS, INCLUDING THE DISEASES AND ACCIDENTS INCIDENTAL TO PREGNANCY AND PARTURITION. Third Edition, revised and modified by Prof. J. F. CRAIG, M.A., M.R.C.V.S. Demy 8vo. Pp. viij. + 528, with 160 Illustrations. Price 15s. net. Baillière, Tindall and Cox, 8 Henrietta Street, Covent Garden, London, W.C.

The first edition of this well-known work appeared in 1878, and the second in 1896. The present third one, in some respects, differs considerably from the earlier issues. Its arrangement has been somewhat simplified—for instance, it is no longer divided and sub-divided into books and chapters, but consists simply of a dozen chapters—and though the general plan of the work remains much as before, it has undergone considerable curtailment. This has been effected partially by omitting the consideration of the diseases of the mammary gland and of young animals, which were included in former editions, and partially also by condensing the remainder of the work. Many details which formerly appeared have been omitted, and as a result we have a distinct alteration in the character and scope of the work. It no longer marks an ambitious attempt to produce a complete and exhaustive work of reference upon veterinary obstetrics, but has been abridged, in the Editor's own words, "so that the work may be used as a short, handy text-book for students, while it may also be helpful and interesting to the veterinary practitioner."

The Editor has discharged a difficult task with considerable skill. Many portions of the work, especially those relating to certain diseases, have been practically re-written, the remainder has been revised and brought up to date, and at the same time the whole work has been judiciously compressed throughout. Upon the whole, the Editor has shown excellent judgment in selecting essential and discarding non-essential matter, and the book therefore will probably be quite as serviceable to the average student or practitioner as were either of its bulkier predecessors.

The work has now become, then, a fair-sized student and practitioner manual upon obstetrical anatomy, physiology, and pathology, including normal and abnormal pregnancy and parturition, the diseases incidental to both processes, and obstetrical operations. In its present modernised and abridged form it will be found to contain all that was most valuable in the earlier editions, and though it has lost some of its completeness of detail which marked those, it will, nevertheless, adequately replace them for all ordinary purposes of the clinician.

W. R. C.

Dick College and the City Veterinary work.

At a meeting of Edinburgh Town Council held in the Council Chambers, on Tuesday, Jan. 16th, the Lord Provost in the chair:—

On a letter from the Secretary, Royal (Dick) Veterinary College, asking that the veterinary work in connection with the Cleansing Department should be entrusted to the College, the Cleaning and Lighting Committee recommended that the request be not agreed to, but that Mr. Dewar be continued to be employed for this work. Mr. Lyon, moving approval, said the Committee looked at this matter purely from a commercial point of view. Mr. Dewar had been the standby of the Farm Committee in no ordinary sense, and they felt that it was their duty to the citizens that they should recommend that the arrangement with Mr. Dewar be continued. He had all the knowledge and experience of the horses required for their purposes and of the market value of the horses. Mr. Bruce Lindsay seconded, saying if Council was going to make the Committee responsible for the staff of 200 horses the Committee should leave it to the discretion of the Committee as to the man who was to advise them.

Mr. Young moved an amendment, pointing out that Principal Dewar had acted not as Mr. Dewar, but as head of the Dick College. He had not been doing this work alone, it had actually been done by the staff of the Dick College. The Council were giving £300 a year for a number of years by way of showing their interest in the College, it would be reversing that policy if they took away work of a yearly value of £130 or thereabouts. Not only would they be doing so, but they would be de-

priving the College of an amount of technical experience that was of enormous importance. Mr. Stevenson seconded, Mr. Macpherson supported the plea on behalf of the Dick College. Mr. Brydon Hogg argued that the Dick College, which was subsidised for teaching, should not indulge in competition in practice with the professional man. Mr. Cameron thought it would be better to stick to the services of the private practitioner. Mr. Stark considered it would be a disaster to their department to make any change, as Mr. Dewar had given them special services. The Lord Provost asked if it was fair to take this opportunity of breaking with the Dick College and giving the work to another person? They would not suffer by continuing with the Dick College, and he intended to vote accordingly. By 27 votes to 18, it was resolved to give the work to the Dick College.—*Edinburgh Evening News.*

Oil and Cake from Sunflower Seed.

Hull is the largest seed-crushing centre in the country, and a supply of sunflower seeds was received there from Odessa during the month. It is understood that the experiment has been successful, and that some of the cakes have been sent to Denmark, and others are being used nearer home, in Holderness. The oil is limpid and quick drying, and will, it is stated, be of great use. The meal derived from the crushing of the seeds will be made up into compound cakes, if the recent experiment proves successful. Sunflowers are grown extensively in South Russia, are very prolific, and yield more than double the percentage of oil derived from Soya beans.—*Hull News.*

PRACTICES FOR DISPOSAL

MIDLANDS. Receipts average £1400 per annum. Present hands over 30 years. Exceptionally good premises, rent £85. Working expenses very light. Easily worked. Fees good. Valuable appointments. Capital required about £1400, including valuation. Good introduction given.

WESTERN COUNTY. Receipts about £600 per annum. In present hands nearly 50 years. Advancing age sole reason for sale.

PURCHASERS ARE REQUESTED to call, or write stating their requirements, as we have numerous Practices on our Register which have not been advertised. *No charge* is made to purchasers.

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

PROSPECTUS, containing "*Hints to Vendors*" and "*Hints to Purchasers*," post free on application.

To Vendors.

WE make *no charge* unless a Sale is effected. If you have a genuine Practice you wish to sell quickly and without publicity we shall be please to place particulars on our Register.

THE VETERINARY RECORD

A Weekly Journal for the Profession.

EDITED BY WILLIAM HUNTING, F.R.C.V.S.

No. 1229.

JANUARY 27, 1912.

VOL. XXIV.

AN ENQUIRY INTO PATENT MEDICINE.

The report of last Council meeting told us that a Parliamentary Select Committee is to be appointed to enquire into the question of patent medicines, and that the R.C.V.S. has decided to ask for representation upon it. The President has received powers to act to this end.

We expect no very radical reform as a direct outcome of the Committee, whatever its report and recommendations may be. The Government derives a large revenue from the sale of patent medicines, and is not likely to restrict it greatly until forced by public opinion. The Press, which so largely shapes public opinion, collectively draws a vast sum from the advertisements of medicine vendors, and many newspapers are sure to unctuously point out the self-interest underlying professional opposition to secret remedies. The last point really is a very serious obstacle. Undoubtedly the public would benefit indirectly by the total abolition of patent medicines. Speaking broadly, they either contain nothing that is likely to be very potent for either good or ill, or something which should only be used under professional advice, and all of them are often used in cases which urgently require professional advice. But though the public would benefit by their suppression, it is quite obvious that the professional man would benefit more directly; and this argument is so plausible that—considering the additional forces of vested interests and public credulity—we expect the traffic in patent medicines to flourish for a long time yet.

Nevertheless, we hope the R.C.V.S. will gain representation on the Committee. The enquiry is certain to have some educative effect so far as nostrums for human use are concerned, and we should like to see it extended to those for animals.

But we wonder what specific veterinary evidence will be forthcoming against patent medicines for animals—we know that medical men can furnish a good deal against those for mankind. A few years ago, for instance, *The British Medical Journal* analysed a large number of proprietary remedies, and published the constituents, estimated cost price, and sale price of each. The whole was issued in a small book called "Secret Remedies," which, needless to say, was practically ignored by the highly disinterested public Press of this Kingdom. Despite that the book did good, and its disclosures will probably be much in evidence before the proposed Committee. It is a pity that no veterinary society is wealthy enough to undertake a similar comprehensive series of analyses of quack medicines for animals. We might then expect some highly interesting revelations regarding the components of condition powders, fever draughts, healing lotions, and infallible cures for distemper.

PARASITIC GASTRITIS OF SHEEP.

Since about the middle of December last up to the present time the flocks in certain parts of the south-west of England have suffered severely from an outbreak of parasitic gastritis, and the mortality is still continuing. In West Somerset the greatest number of deaths has been observed amongst ewes, and these of all ages, though lambs of a year old have been affected; one breeder I have in mind has suffered severe loss in his pedigree yearling rams. What loss has been incurred amongst this season's lambs has been chiefly owing to the death of the mother with consequent starvation of the young lambs, in large flocks it being impracticable, in some cases, to bring up the sucking lambs by hand. In cases where the lambs have been old enough to look after themselves they have survived. In this neighbourhood the Dorset horned sheep are largely kept, and many cases have been observed amongst them, but the disease has not been confined to this breed, for Down sheep and crossbreds have been equally affected. This outbreak, at least, cannot be said to be the direct result of poor feeding, as in the majority of affected flocks to which my attention has been called, the sheep have been fed exceptionally well, to make up for loss of condition sustained during the drought of last summer. Losses of 70, 50, etc. have been incurred in certain flocks, but I have not yet been able to arrive at an average percentage. Lambing appears to have some influence in determining the incidence of the disease, as it has only been seen amongst ewes at various periods after that act has occurred, in fact one owner has affirmed that the most rapidly fatal cases in his flock have been in ewes that have had twin lambs. I give this statement for what it is worth.

I have in mind a flock where lambing has not yet commenced and no cases have occurred, though in the centre of the affected district. It will be interesting to observe whether this flock is attacked when lambing starts, but as the owner has decided to take advantage of his neighbours' experience and treat his ewes for gastric parasites at once, it is to be hoped that no confirmation of this statement will be arrived at. It appears feasible that the act of parturition and subsequent lactation may make such demands on the system as to lower it sufficiently to render it less able to withstand the attacks of the parasite.

Epidemics of this nature are usually said to occur in flocks pastured on low lying and marshy grounds, but my experience in this instance is directly opposite; the outbreak has affected flocks stationed on

the hills and elevated ground, and where there is little or no stagnant water, the water supply being almost entirely from springs or wells. If these flocks have been fed on contaminated pastures during the past year it is certain the long drought which has been experienced here has not had the effect of destroying the parasite in that stage of its life history which is passed externally to the body of its natural host, and this may be, perhaps, additional evidence as to the resistance of the egg or embryo to heat and dryness, on the supposition that no intermediate host is necessary to its existence, and that it spends that part of its life cycle in the open. The more or less continuous warm rains following the drought undoubtedly have been responsible for the renewed activity of the parasite, and favourable to its development in anticipation of ingestion by its favourite host.

Symptoms.—In cases where the ewe is still suckling lambs the first noticeable symptom is that the latter are doing badly, and then, if the ewe be examined, it is found that she has partly or entirely lost her milk, and in a short time she goes dry. Coincident with this is rapid loss of condition, elevation of the wool along the spine, cessation of rumination, and then profuse, watery diarrhoea, which is not intermixed with blood or mucus. In most cases there is oedema of the intermaxillary space and swelling of the upper lip. The visible mucous membranes are pale and anæmic, and there may be some elevation of temperature at the early stages. There is pronounced craving for water, the sheep taking every opportunity of drinking. The appetite rapidly fails, great prostration sets in, and then death. The course of the disease varies from three days to about a week.

Post-mortem.—On removing the skin and incising the body there is a noticeable absence of fat. In most cases the heart shows a gelatinous effusion beneath the pericardium at the base. The lungs, in some cases, may show a more or less severe condition of parasitic broncho-pneumonia, due to the presence of the *Strongylus rufescens* and *S. filaria*. In all instances in which this condition was found I was able to demonstrate both parasites. Cough, however, is not a noticeable symptom during life, although it may be observed in affected animals.

It is, of course, in the abomasum that the principle lesions are found, though it will be noticed that the other three divisions of the stomach contain ingesta rather moister than usual. Before incision the abomasum may be more or less distended with gases, but it is never tympanitic when fresh. Its contents will be found very fluid and of a dirty olive-green colour. The extent to which the mucous membrane of the abdomen is affected varies somewhat according to the severity of the attack. In one case the whole of it may be of a dirty claret colour, in others the discolouration may be confined to areas of varying size. That part of the duodenum nearest the stomach may show inflammatory areas, but I have never found the small intestine uniformly affected, or affected to any great extent. The large colon may also show some inflammatory areas, but there again they vary in

size and degree. The cæcum may contain fluid contents, but the intestine, as a whole, is empty.

Diagnosis. Precise diagnosis is determined by microscopic examination of the mucous membrane and fluid contents of the abomasum. On allowing some of the latter to stand in a glass tube or bottle the solid particles gradually sink to the bottom, and the upper stratum will then be observed to be distinctly blood tinged. For my own part, I have not found naked eye examination of either the mucous membrane or the stomach contents satisfactory, as the minute parasites are extremely difficult to distinguish when mixed with *débris* and small strands of vegetable fibre. It is far better to take a scraping from the former, or a drop or two of the latter, and place it under the low power of the microscope when the causal parasite may be easily seen.

The parasite responsible for the epidemic in question is the *Strongylus cervicornis*, M'Fadyean's excellent description of which will be found in the second edition of Neumann's *Treatise on Parasites*. In the cases I have examined I have found a practically pure infection with this parasite, but an occasional, though rare, strongyle of another species may be met with. In the worst cases they have been extremely numerous, every drop of the contents of the abomasum may reveal some, and if a very small portion of the sediment which forms on standing be examined many may be found intermixed with flocculi of mucus and vegetable *débris*. They may then be easily picked out with the point of a fine needle and transferred to clean water for a more minute examination. Closer inspection of the sediment will show many ova, and these, according to my experience so far, have always been in the morula stage, at different degrees of segmentation. I have not yet been able to find eggs in which the form of the future embryo could be distinctly traced, but on the other hand have found numerous free forms which appear to be embryos. In this respect, therefore, my experience is somewhat different to what was observed in the outbreak of gastritis due to this parasite detailed in Neumann. It would appear to be possible that the embryonic forms are those recently ingested by the host, and that the eggs which are emitted by the sexually mature, fecundated female worm within the body of the host do not attain any great degree of development therein. I have not been able to see any egg containing an embryo so far advanced in development as may be observed in those of the *S. filaria*, for instance, of the bronchi. The mature parasites vary greatly in length, the average in those that I have observed being rather less than that given by M'Fadyean. Those attached to the mucous membrane have been found to be shorter than those free in the stomach contents, possibly the latter are more advanced in development.

Treatment. Unfortunately I was not consulted till large numbers of sheep had died, and the disease was well established, but, provided the animal is not at the last stage of the disease, I think treatment should be attempted, and a fair amount of success looked for. I have found the arsenic and iron mixture recommended by Law very useful, as

well as the 1 per cent. solution of Iysol in half pint doses as suggested by M'Fadyean, but in the latter case some owners have asserted that severe constitutional effects are seen after administration—violent quivering of the muscles, and immediate death in some instances. I am of the opinion that these unfortunate cases are those in which the lungs were affected and the animal practically moribund. But other owners have not observed this result, and it may probably be due to not very careful drenching.

Ideal prophylactic measures are very difficult to adopt, at any rate here, but as the duration of life of the egg or embryo in the open is probably limited, it would, if possible, be as well not to graze sheep on pasture which has been contaminated with the excrement of affected animals for three years or so; perhaps, too, the periodic administration of suitable anthelmintics is indicated. It will be interesting to observe if later on in the year the lambs which are feeding with their affected mothers are attacked; it would seem, at any rate, that they are running considerable risk, and will continue to do so if they are again fed on this pasture when the grass grows again in the spring. Probably the future of those sheep which are folded on turnips, etc., on arable ground, which will in its turn be cultivated, will be of a healthier nature.

E. G. HASKELL.

ABSTRACTS FROM FOREIGN JOURNALS

ECHINOCOCCOSIS AND DISTOMATOSIS IN THE LIVER OF THE PIG.

Chrétien, sanitary veterinarian of the department of the Seine, says that, among the lesions which are encountered in the liver of the pig, a certain number, which have been very frequent this year, present themselves under the following aspect.

The lesions assume the form of whitish, rounded, slightly projecting tumours, varying from the size of a pea to that of a nut. They are distributed unequally, and by preference are superficially situated immediately underneath Glisson's capsule. When incised, they are found to be formed of a thick envelope of fibrous tissue surrounded by the hepatic parenchyma, and containing a small internal cavity, which holds sometimes a few drops of colourless or dull liquid, and sometimes, on the contrary, a small quantity of pus, which is more or less thickened, white or yellowish white, and sometimes calcareously infiltrated. The affection has no influence upon the hepatic lymphatic glands.

In some of these lesions, remnants of membrane are found mixed in the pus, and sometimes hooklets of *Tenia echinococcus*. The lesions are caused by encysted echinococci undergoing degeneration.

The liver of one pig, however, showed lesions having the same situation and exterior aspect as those just described, but quite different in their origin. A close examination showed some other differences between these and the preceding lesions, which Chrétien proceeds to indicate.

The thick fibrous envelope contained a small quantity of clotted material, brownish in colour, which could be enucleated fairly easily; the interior of the envelope had a shagreened aspect. Microscopical examination of the contents of these cavities revealed neither specific microbes nor parasites.

Sections cut at different points of these lesions showed them to be cysts having a fibrous peripheral envelope and a centre formed of a mass in which some cellular debris and some areas which had undergone calcareous infiltration could be distinguished. In places the calcification had even invaded the internal portion of the fibrous envelope. In the external area, the hepatic tissue showed very marked sclerosis, which gradually diminished as the lesion became more remote.

Two lesions of this liver were in a less advanced stage. Their fibrous capsule was not so thick, and enclosed a small cavity filled with brownish pus, into which opened a fine biliary canal, slightly sclerosed and partially obliterated. One of these two lesions contained a large adult specimen of *Distoma hepaticum*; the other contained three. The parasites were paler than those found in the ox and sheep, and the pus in which they were immersed contained no eggs of distomes.

In the remaining portion of the liver the biliary canals had undergone neither dilatation nor chronic peripheral inflammation; and they contained no parasites, either young or adult.

Chrétien concludes that the lesions in this case were consecutive to the penetration of the biliary canals by distomata in the embryonic stage. The presence of these parasites had caused an intense inflammation, resulting in the encystment, arrest of development, and degeneration of the parasites.—*L'Hygiène de la Viande et du Lait*,

HAY FEVER IN HORSES.

Walther, of Leipzig, discusses an affection which he regards as equine hay-fever, and describes one recent outbreak of it.

Last summer, in a garrison and its surroundings, a catarrh of the upper air passages attended with violent coughing appeared among the horses of the civil population, all the affected animals showing quite similar symptoms.

This catarrhal cough also raged among the horses of the cavalry regiment stationed at the place, and spread almost uniformly over all its squadrons. One squadron was especially severely affected, and in this 80 horses showed these symptoms. The cough was so violent, persistent, and painful, that horses attacked by it while in progression stood still, and assumed a crouching position, bowing towards the ground. The visible mucous membranes of the head were violently reddened and showed inflammatory swelling. Watery, slimy, lacrymal fluid flowed in great quantity from the eyelids, while a very great deal of thin mucus, mingled with thick flakes, came from the nostrils. The discharge was especially violent after the attacks of coughing. In five horses the condition was especially severe, the conjunctival being so swollen as to bulge out and project.

The circulatory system showed no abnormality; and the internal temperature rose to 102.2 F. and upwards in some horses only. The affected animals showed more or less dulness; but food and drink were taken, though more slowly than usual. The condition lasted one to three days, in some horses longer, and the animals recovered surprisingly rapidly. No unfavourable after-effects were observed.

This hay fever or hay catarrh, Walther adds, commences in the early summer at the time of the blossoming of the grass, and has passed its maximum by the time of the corn-harvest. It is not seen every year; and in many localities it seems to be unknown. The great number of the affected horses, the painful violent cough and copious secretion from the mucous membranes of the head, with the rapid recovery and benign termination, are the typical features of hay fever.

Walther attributes the condition to the irritation produced by the pollen of many species of grass plants, which are blown upon the mucous membranes of the eyes and respiratory organs and adhere there. He remarks that he has already briefly recorded the appearance and the symptoms of equine hay fever years ago; and he adds that Prof. Haubner, in his lectures, has incidentally mentioned the appearance of peculiar catarrhs, the etiology of which is still insufficiently understood, at certain periods of the year.—(*Berliner Tier. Woch.*)

[Has this condition been seen in any part of the United Kingdom?—*Trans.*]

AN EMBRYONIC FILARIA CAUSING SYMPTOMS OF DOUBINE.

Darmagnac reports (*Rev. Gen. de Méd. Vét.*) a case of a stallion shewing a cold and insensitive engorgement of the prepuce, which increased and reached the dependent portions of the abdomen. At the same time, œdematous pimples were observed upon the neck and shoulders, and upon the croup. Four days later, a circular patch, offering the objective characters of a lesion of dourine, appeared upon the ribs upon the right side.

These lesions persisted without notable change for three weeks, then retrogressed rapidly and disappeared completely in a few days. On the surface of the prepuce, however, traces of the condition remained in the form of unpigmented spots giving the region a peculiar marbled aspect.

In the blood taken from this horse, both that taken from the preputial swelling and from the cutaneous lesions (pimples and circular patch) a microscopic parasite was found. This possessed great mobility, could be clearly distinguished from the trypanosome of dourine on account of its much greater size, and appeared to be an embryonic filaria.

The parasite was from 200 to 250 micro-millimetres long—thus roughly about ten times the length of the trypanosome of dourine. In shape it was vermiform, rounded at its cephalic extremity, and extremely attenuated at the other. In colour it was clear white, with rather dark spots distributed

over the whole body. It was extremely rapid in its movements, which were effected by a sort of reptation; sometimes it attached itself to the glass by its cephalic extremity, and its tail then showed rapid oscillatory movements, which violently dashed about the blood corpuscles.

Whatever the hour of the day or night at which the blood was removed and examined, four or five of these hæmatozoa were generally found in each preparation. Their disappearance in the blood coincided with the disappearance of the lesions.

Injections of the blood made into the rabbit and the dog gave negative results.

The stallion received two subcutaneous injections of five grammes of atoxyl, but it was impossible to say whether these had had any influence upon the evolution of the disease.

The parasite was probably an embryonic filaria, but the author was unable to determine either the adult form or the agent of transmission.—*Annales de Méd. Vét.*

ANTISTREPTOCOCCIC SERUM IN THE TREATMENT OF PURPURA HÆMORRHAGICA.

Verlinde, of Anvers, says (*Bulletin de Méd. Vét. Prat.*) that the polyvalent antistreptococcic serum prepared by the Pasteur Institute of Paris is exceptionally valuable in the treatment of purpura hæmorrhagica. For years past he has employed this serum in the treatment of pneumonia, strangles, and purpura hæmorrhagica, and is completely satisfied with the results he has obtained.

It is in purpura hæmorrhagica that this serum has given especially remarkable results, which are so striking that Verlinde regards it as a "precious specific" in this disease. His mortality before using it was 50%, but during the four years that the treatment has been in use, he has not lost a single case.

Injected at the very onset of the purpura hæmorrhagica, the serum aborts the disease. Injected later, it controls the production of œdemas and favours and accelerates their resorption. The nasal petechiæ become pale and disappear much more rapidly than under other treatments. Nearly always the injection is followed by a fall of temperature, and the horse appears livelier and eats better.

Verlinde's usage is to give two injections daily, each of 10 c.c. of the serum, for the first two or three days of the illness. Afterwards he gives one injection daily for about a week longer, according to the progress of the case.—*Annales de Méd. Vét.*

W. R. C.

Veterinary Laws in Indiana, U.S.A.

Everyone desiring to practice veterinary medicine and surgery in Indiana, must, under the laws of that State as now amended, pass the State Board of Veterinary Examiners. Prior to the amendment, graduates from reputable college were given licences on presentation to the licencing board, of their diplomas, and they could demand same, even if they could not pass the State board.—*A.V. Review.*

INDIAN CIVIL VETERINARY DEPARTMENT

THE ANNUAL REPORT OF THE VETERINARY OFFICER INVESTIGATING CAMEL DISEASES: FOR THE YEAR ENDING MARCH 31ST, 1911.

The Report, written by Mr. A. S. Leese, the specially appointed investigator of camel diseases of the C.V.D., is now to hand. To an English veterinary surgeon it is interesting reading; to one in India, actually concerned with the treatment of camels, it is much more.

For the first three months of the year under report Mr. Leese was upon privilege leave, his place being filled by the Inspector-General of the C.V.D. For the remaining nine months Mr. Leese was in charge, spending the whole of this time in camp. Building operations for the accommodation of the veterinary officer and his staff were in progress during the year, but were not completed at its conclusion; and it is not surprising therefore, to see it laconically stated in the report that "The want of accommodation has again greatly hampered the work." Nevertheless, a great deal of good work has been done.

Surra, of course, is by far the most important disease of camels. The work connected with it—apart from the actual campaign against the disease as it exists in Camel Corps—falls naturally into two divisions, viz., investigations regarding transmission, and experiments in treatment. In both these directions, substantial progress has been made.

Observations upon transmission have been made chiefly upon tour—and here it may be remarked that more than one-third of the veterinary officer's nine months' work was spent upon tour. These observations have consisted partially in the examination of camels in the different areas visited, and partially in the study of the local conditions and of the distribution of biting flies. The last-named research has resulted in suspicion falling upon a hitherto disregarded biting fly, a *Lyperosia* (*Lyperosia minuta*, Bezzi), as a possible transmitter of surra in addition to the already recognised ones *Tabanus*, *Stomoxys*. Only once before (in Rhodesia amongst cattle) has *Lyperosia* been suspected as a transmitter of trypanosomiasis; but Mr. Leese's reasons for again suspecting it (which include the discovery of surra certainly contracted in a locality where neither *Tabanus* nor *Stomoxys* could be found, by *Lyperosia* was abundant) are certainly strong ones. Mr. Leese, writing in May last, states his intention of instituting experiments to definitely test the possibility of transmission by *Lyperosia*; these were to take place in July, and the question may well be settled by this time.

Very material progress has been made as regards the treatment of surra in camels. This portion of the year's work has mainly consisted in the detailed working out of the system of drug treatment which had yielded the best results in former years, viz., a combination of atoxyl (intravenously), tartar emetic (intravenously), and sodium arsenate solution (per os). The intervals and doses of these drugs, and the methods of administration, have now been studied so far that Mr. Leese states that "the amounts of each drug that the camel can stand given in these different ways is now pretty well defined," and he cautiously adds that "it seems as though cures have been obtained." Caution in this latter particular is very necessary, partly from the recurrent nature of the disease, and partly from the fact that spontaneous recoveries may occur, and indeed "are fairly frequent in camels carefully looked after by their owners."

Considering these circumstances, Mr. Leese's view is that "if a number of camels treated by one experimental method not too dangerous were to go six months under daily blood examination without relapse, it would

be good enough to recommend for trial in Camel Corps; if besides some had gone 15 or 18 months without relapse, it would give additional confidence." This sentence well shows the enormous amount of routine work involved in working out the problem of surra treatment. The year's work cannot yet be said to be conclusive; but, at the time the report was written, two camels treated by the three drugs mentioned above had each exceeded five months without relapse, and a third had exceeded 15 months. These results were obtained by a rather long treatment covering 37 days; and, as only four camels were subjected to it, the three apparent recoveries must be pronounced very encouraging indeed.

There are other short notes of interest in connection with surra, such as an experiment upon the incubative period, others—negative in results so far—upon the possible protective power of the serum of spontaneously recovered camels, and a description of a native clinical diagnostic test practised by the Rehbaris, and based upon a characteristic smell of the camel's urine during paroxysms of fever arising from surra. But surra is by no means the only subject figuring in the report. Some parasites and parasitic diseases are dealt with, notably *Linguatula* larvae and their association with peritonitis in the camel, and parasitic bronchitis due to *Strongylus filaria*, which, though not uncommon in Egyptian camels, seems to be rare in those of Northern India. Pus in the frontal sinus, due usually to traumatism from blows, is also considered in some detail; the salient points in the anatomy of the frontal sinus in the camel are described, and directions are given for a rational method of treatment, viz., trephining.

Lastly, the report concludes with a variety of hints upon the management and treatment of sick camels, with some special details relating to the diagnosis of various conditions common in these animals—such as pulmonary abscess as a sequel to lobar pneumonia, and "sore mouth," which is somewhat liable to be mistaken for foot-and-mouth disease. This section terminates with a list of drugs suitable for the camel, and their posology; the drugs recommended all being well known in bovine practice, and the doses but little larger than those given to cattle. Practically this concludes a report which, from end to end, is replete with evidence of good work in a subject in which good work has long been sadly needed.

Appended to the report is a short review of its contents by Lieut.-Colonel G. H. Evans, the Officiating Inspector-General of the C.V.D. This is altogether commendatory of the work done amongst camels during the year, and speaks in especially hopeful strain of the prospects regarding a cure for surra. We cannot conclude our brief summary of the report more fitly than by quoting Lieut.-Colonel Evans' final paragraph of personal reference to his subordinate. "Mr. Leese has been most energetic and unremitting in his labours to advance our knowledge of the diseases of the camel. Considering his work has been carried out very often in trying circumstances, the success achieved is highly commendable. I consider we are greatly indebted to him not only for the zealous manner in which he has carried on his work, but also for the progress made."

Dr. VERANUS A. MOORE, the Director of the New York State Veterinary College, was unanimously elected a Foreign Corresponding Member of the Société Centrale de Médecine Vétérinaire, Paris, at their sitting in November last.

In the Western section of the United States a temperature of 50deg. below zero was recorded on January 6th. Many persons were frozen to death, while thousands of cattle and sheep perished.

SWAMP FEVER IN HORSES.—By L. VAN ES., E. D. HARRIS and A. F. SCHALK. Bulletin Number 94. North Dakota Agricultural Experiment Station (Department of Veterinary Science). Fargo, North Dakota, U.S.A. September, 1911.

This "bulletin" is really a lengthy and comprehensive record of research work by these three authors, who are the veterinarians attached to the staff of the North Dakota Agricultural Experiment Station. It concerns a disease widely known in America as "Swamp Fever," which certainly causes considerable loss among horses, but is as yet very imperfectly understood. The value of the publication, however, is not confined to America, for there is good reason to believe that the same disease, under another name, has long been recognised in Europe.

Various French writers since 1843 have described an equine disease which has been generally called "infectious anæmia," and within the last thirty years a number of reports have been published upon what seems to be the same condition in various parts of Europe. Zschokke, Fröhner, Ostertag, Vallée and Carré, and Hutya and Marek, are among the best known writers upon the subject; and the disease has been recognised in France, Switzerland, Belgium, Germany, Sweden, and Hungary. It is not quite certain that this European disease is identical with the American swamp fever, but there are very strong reasons for supposing it to be so.

It is not absolutely known when and where swamp fever first attracted attention in America. It seems to have been prevalent in the Red River district for thirty years at least, and thence to have spread into Manitoba and parts of the North-west territories. Since then it has been described in many parts of the American continent, from Canada, where Torrance and Rutherford, among others, have described it, to so far south as Texas. The same disease, or one clinically corresponding to it, has even been reported from the Panama Canal zone. Here, again, it does not seem quite certain that all these reports relate to one and the same condition, but the existence of a single widely spread and serious disease is unquestionable. The amount of loss it occasions is also rather uncertain, as diagnostic difficulties render many of the present statistics of doubtful value. But its rate of mortality is certainly very high, and its continued geographical extension would be a very serious thing indeed.

The publication summarises the accounts which various authors have given to the disease both in Europe and America. Very different views have been advanced regarding its ætiology. Some have described micro-organisms in connection with it, and a number of surmises have been advanced regarding predisposing causes—one, not unsupported by clinical evidence, is that helminthiasis is a potent factor in this direction. It now seems definitely proved that the disease is infectious, and is caused by an ultra-microscopic virus which is transmissible either by the blood or by the digestive tract.

The symptoms present some variation, different authors dividing the cases into an acute and chronic type, or into acute, subacute, and chronic. Generally the disease may be described as an irregularly intermittent fever, with a progressive anæmia, rapid emaciation (though the appetite is usually keen), cardiac weakness, and prostration. Œdema and impaired locomotion, especially of the hinder parts, are often seen, as are also a number of other symptoms, such as polyuria, albuminuria, and a thin sanguineous nasal discharge. The duration of the affection varies greatly—from a few days to months, or even years.

Post-mortem appearances are varied, and not very characteristic. They include degenerative changes in

the various parenchymatous organs, petechiæ and ecchymoses of the serous membranes and endocardium in particular, œdemas, and alterations of the lymphatic glands and the bone marrow. These changes seem to indicate a general intoxication or septicæmia, and the present authors point out that secondary infections probably have a large share in inducing them.

Many different lines of treatment have been attempted, but none so far seem to have proved of marked value.

The present authors' results, which are reported in considerable detail, are in the main confirmatory of those of previous workers, but some of their conclusions seem to be important and suggestive additions to the existing knowledge. They find that swamp fever is an infectious disease, transmissible by subcutaneous and intravenous injection, and by ingestion. The virus is contained in the blood and urine of affected animals, but not in the faeces. So far the virus has only been demonstrated in an ultra-microscopic form; but the authors point out that this may be only one stage in its evolution, and therefore advise continued search for a micro-organism. The virus resists the severe freezing weather of North America. Possibly it may be transmitted by means of parasites and insects, but the authors suggest that animals contracting the disease naturally do so by the ingestion of food or water contaminated by infected urine. The chief and most constant symptoms, the authors find, are fever and albuminuria, and one of their most notable observations is the fact that many cases terminate *without* marked reduction in the red blood cells. This undoubtedly suggests that many cases of swamp fever have hitherto escaped diagnosis.

The authors also find that an animal's blood may remain virulent for fully thirty-five months after infection without any clinical symptoms being shown; and probably these non-clinical "carriers" play a great part in infection. So far, the authors can advise no preventive measures beyond such ordinary ones as the destruction of diseased horses, segregation of suspects, prevention of any contamination of food and water by urine, and so forth. They have tried trypan blue and atoxyl in the treatment of the disease, but find both useless.

The "bulletin" is a careful and valuable contribution upon a very obscure disease, and well shows how much there is still to be learnt regarding it. It also undoubtedly suggests that the disease may be much more common and widely spread than has yet been supposed, and on that account also it deserves to be widely known in America and Europe alike.

W. R. C.

CENTRAL VETERINARY SOCIETY.

A general meeting of the Society was held at 10, Red Lion Square, on Thursday, January 4th, the President, Mr. R. J. Foreman, occupying the chair. The following Fellows signed the attendance book: Messrs. J. C. Coleman, Alexander Crabb, F. H. Sanderson, J. F. Macdonald, Prof. G. H. Wooldridge, G. H. Livesey, J. Willett, R. Eaglesham, J. W. McIntosh, Sydney J. Slocock, B. Gorton, N. Almond, G. Gordon, Vety.-Capt. C. H. H. Jolliffe, A. L. Wilson, W. Perryman, T. S. Price, A. L. Butters, H. D. Jones, R. Bryden, A. Neish, James A. Gosling, C. A. W. Cunningham, J. A. G. Gosling, W. Willis, A. Rogerson, and Hugh A. McCormack, hon. sec.

Visitors: Messrs. J. Soulsby, T. J. Symes, J. W. Richardson, and T. W. Lloyd.

On the motion of Mr. McIntosh, seconded by Prof. Almond, the minutes of the previous meeting were taken as read and confirmed.

CORRESPONDENCE.

Letters regretting inability to attend the meeting were announced from Messrs. Charles Roberts, J. T. Angwin, and E. Lionel Stroud.

A circular letter enclosing the agenda of the Royal Sanitary Institute Congress in York on July 29th to August 3rd inclusive, and inviting delegates to attend.

A letter inviting the Society to be represented at the Milk and Meat Hygiene Congress, to be held in Paris in October next.

It was agreed to place the communications upon the agenda of a future meeting for discussion.

SPECIMENS.

Mr. EAGLESHAM exhibited a fracture involving the lower series of bones of the off hock, the cuboid, cuneiform magnum and medium in an aged mare, the result of running away and falling over a bank into a roadway. After getting up it walked for about thirty yards, and falling again rose with some difficulty, when it showed great lameness and all the symptoms of fracture; it had to be destroyed. He pointed out that there were two cuneiform parvum bones in the hock, each with separate articular surfaces. The parvum bone is generally found as a single one.

He also exhibited a specimen of a mixed calculus from an aged mare that had been subject to slight attacks of colic about twice a week for the last twelve months. The calculus escaped into the floating colon and caused perforation of the bowel, from which the mare died.

The PRESIDENT showed a case of ringbone, pyramidal, and navicular disease in a horse which had been working up to the time it was stopped by the police. The animal being unnerved the case was dismissed on the undertaking being offered that the owner would have the animal destroyed at once. The disease was very extensive indeed, and if there had been any nerve supply to the foot the President thought it would have been very painful.

He exhibited also a portion of calcareous material which had been taken from the leg of a mare. There was no evidence of the mare having been kicked, or being a kicker. She had what seemed to be an attack of lymphangitis, which became localised under the thigh. For about three weeks little progress was made, and as there was evidence of suppuration he opened, obtaining pus. The place, however, did not diminish in size, and that day he had explored the wound and obtained what seemed to be calcareous material. Whether it was a plugged lymphatic (as it followed its course) that had become calcareous he did not know.

Mr. PERRYMAN thought the first case shown by the President involved ossification of the tendon.

Prof. WOOLDRIDGE asked whether it was considered to be mechanical lameness.

The PRESIDENT thought it was absolutely mechanical lameness, as the animal did not take the slightest notice of whether he was standing upon it or not. When the animal moved the toe cocked up, but he could put it perfectly flat and stand perfectly well on it, and in the stable he stood quite naturally.

Prof. WOOLDRIDGE said it seemed to him it would not be a bad thing to have an expression of opinion from the Society with regard to the possibility of cases of mechanical lameness. In police courts veterinary surgeons often found themselves opposed to people who maintained it was impossible to have mechanical lameness, and that the lameness must be always associated with pain.

The PRESIDENT said the Magistrate, as soon as he saw the horse, dismissed the case. He (the President) had kept the animal alive overnight to be produced again the next day, because there was a little dispute as to

whether the horse was unnerved or not, but as could be seen from the specimen there must have been very little or no nerve supply, or there would have been evidence of great pain.

Prof. WOOLDRIDGE said he should not like to say there was no pain in that particular case.

The PRESIDENT said he happened to know that the horse was unnerved because he examined him four years before, soon after the operation had been done.

Capt. JOLLIFFE asked whether there was any difficulty in diagnosing the fracture in the case shown by Mr. Eaglesham.

Mr. EAGLESHAM said the animal stood on three legs, and crepitus could be obtained.

PROFESSIONAL EVIDENCE IN POLICE COURTS.

Mr. McINTOSH referred to new Animals Protection Act which had just come into operation, and said he was sure every veterinary surgeon welcomed any measures which were likely to prevent cruelty and promote the comfort of our domestic animals; but he objected very strongly to the methods adopted in bringing about prosecutions. He thought it would be well to form some organisation and make representation to the proper quarter to see that the veterinary profession received better treatment at the hands of magistrates. At the present time it was a disgrace to the Bench. Personally he was always ready to meet a man on level terms, but unfortunately that could not be done in the Police Court, and he strongly objected as a professional witness to the magistrate or his clerk trying to put words into his mouth. He was satisfied that if representations were made some alteration would be brought about.

Mr. WILLETT proposed that the subject should be placed upon the agenda for discussion at the next meeting, and moved: "To discuss the unfair treatment meted out to our profession when giving expert evidence at the Police Courts."

Mr. COLEMAN seconded the motion, which was carried.

Prof. WOOLDRIDGE read a paper on Botriomycosis.

The PRESIDENT said he could only remember having the ordinary cases of shoulder, elbow, and scrotal troubles; excepting one case on the shoulder of a three-year-old, beginning about the supraspinous process and going forward up the neck under the skin. On dissecting it right out he found it to be a long pipe. The wound was eight inches long. The case did very well. He had not had very much result from the internal administration of Pot. iod., but he had only given a dose of half a dram once a day, which was rather different from an ounce dose. With regard to putting the chain on the cord high up, he had had a case where he had not been able to get the chain past the enlargement, and had had to get up as far as he could reach; the case had done alright and there had been no recurrence. For shoulder tumours, the best thing to use was the knife when the inflammation had subsided. In a fortnight a very large tumour would disappear if the centre was reached and filled with Biniodide ointment. In three weeks a horse with a tumour about as big as a man's head would be able to get to work.

Prof. ALMOND thought the disease must be more common in town than in the country, because in his forty years experience only one case had come under his notice, and that was a case of the cord. He did not remember meeting with any shoulder tumours that caused any trouble; tumours of the shoulder he had seen he usually attributed to nips and injuries. He had used ligatures occasionally in his practice, and his method had been always to leave long ends extending outside the incision. Although that might be source of danger in conveying infection, he had never had any trouble. He thought that if the clams referred to as being lost had been

secured by some of ligaturing material they would certainly have been better under control.

The PRESIDENT said old practitioners used to plunge a hot pointed iron into the centre of a tumour, but he thought it was much quicker to use a knife, and it caused much less pain. By making a big gash the centre could be reached at once, and there often was not more than half a thimble full of pus. Elbows were much more difficult to heal.

Mr. SANDERSON asked Prof. Wooldridge if he had any statistics to show after which method of castration scirrhus cord most commonly occurred. A very experienced and instructive practitioner with whom he served his tutorship had performed castrations by clams, écraseur, and the actual cautery, and now resorts to the last method entirely. He always opens the scrotum with the knife, and after cauterising the end of the cord he enlarges the scrotal wound—asepticises the parts well, and then takes hold of the end of the scrotum and pulls it out as far as possible to assist the spermatic cord to proceed backwards into the canal. By using the actual cautery and afterwards trying to ensure the return of the cord into the canal, he contends that he has now fewer cases of scirrhus cord.

He had seen a case of botriomycosis in the udder in a five-year-old mare, whose foal had died six months previously. The udder began to swell and became very painful, and on being opened a sticky mucoid discharge came from it. It healed up apparently, but a month or two later started again, and on being opened emitted the same characteristic discharge. After this she was treated internally for a few days, and received an ounce of Liq. calcis iodinate twice a day in water, followed immediately by two drams of Pot. iodide in a little water, and she did well after. The owner asked him whether it would be safe to put her to the horse again, but he told him no. As a student, doing *locum*, he remembered a horse that showed very considerable constitutional disturbances. There was a large, painful swelling in front of the shoulder, and he thought it was going to be just an ordinary large abscess. The temperature was 103 and the pulse about 70. The part was fomented and a little blister applied. About four days afterwards he was told by the veterinary surgeon, who had returned and incised it, that it was botriomycosis. He made just a clear incision into its depths, and the case did alright after. In the last two or three cases that had come to his notice, especially shoulder cases, all he had done was to incise them clean to their depths, without dissecting anything out, and they had all done well.

Mr. MCINTOSH had some experience of scirrhus cord when in country practice and had found it much more likely to follow castration after the use of the écraseur than by other methods, and accordingly he abandoned the chain and used the caustic clam, dressing with Hydrarg. perchlor. After that he had very few cases of scirrhus cord supervening upon castration. The removal of these tumours from the scrotum was to him a matter of considerable trouble owing to the amount of hæmorrhage and the difficulty there was in dissecting them away from the walls of the scrotum, to which, as a rule, they are firmly adherent. Once this was done, then removal was comparatively simple.

In one particular case he could not get the chain sufficiently far up to get to the end of the thickened cord, but he took away all he could get at, plugged and dressed in the ordinary way, and the animal seemed to get all right. About twelve months afterwards this animal died of what appeared to be colic, and post-mortem revealed an enormous tumour in the abdomen just inside the inguinal canal.

With reference to shoulder tumours, their removal was a comparatively simple matter, and there was nothing very special in the way of after-treatment, further than

to see that the wound was kept healthy and that it was not allowed to close up too quickly.

Capt. JOLLIFFE mentioned that in India he had a case which he took to be botriomycosis of the udder. The mare had a large suppurating tumour of the udder which seemed to be increasing in size, and she was operated upon by the late Capt. Southey, A.V.C., he (Capt. Jolliffe) administering the anæsthetic. Both halves of the udder were involved, and a mass about half the size of a man's head was removed, partly by the knife and partly by the écraseur. The wound healed favourably, and as far as he could remember there was no recurrence. The case was examined microscopically, but neither of them being bacteriological experts the examination was not conclusive. The pus was gritty. There were quantities of cocci of several descriptions, and they could not be absolutely certain about the disease. With reference to the administration of chloroform and the possibility of more hæmorrhage under such conditions, he should like to know whether it had been found in human surgery that there was more hæmorrhage in a patient under an anæsthetic. He was inclined to believe it was largely a matter of imagination amongst veterinary surgeons. If more hæmorrhage accrued from the use of an anæsthetic in animals it would surely apply equally in connection with human surgery. He had inquired of surgeons, and as far as he could make out no such idea has ever existed, except in veterinary surgery.

Mr. PERRYMAN said there were many cases seen in London, and he was particularly pleased to hear Prof. Wooldridge say with reference to shoeball, fistulous withers, and tumours of the shoulder, but they are not all due to botriomycosis. Personally he thought that a large number of big tumours of the shoulders were not due to botriomycosis but to direct injury. Shoulder infection was generally very clearly shown by little pustules all round the skin, and the pus coming from little nodules and that was a different sort of thing from big tumours which came up within twenty-four hours. He had been particularly interested in the iodine treatment. Some years ago an assistant of his who had just come from college, treated some of the nodules on the shoulder with iodine injections, but the case hung on for five or six weeks. The knife was then used and it was well in a fortnight. Sections of the particular tumour were made afterwards, and it was found that wherever iodine had been injected there were necrotic patches, the tissues had become necrosed. Since then he had never used an injection of iodine for such cases. He thought it would be worth while on a small scale trying the grooved director to see if a little of the stuff could be got inside. In the previous week he had seen a horse which had a huge thickening behind the knee, with dozens of little nodules, the skin being thickening about three or four inches, and he thought that was a case of botriomycosis. There were similar thickenings in the region of the hock and one on the outside of the off hind fetlock. In his opinion that would be a good case for experimental treatment, although it would be beyond iodine injections as there were about a hundred or two hundred nodules. He would like to know if Professor Wooldridge could suggest some form of treatment in such a case.

Mr. MACDONALD said he had had a rather unusual case of botriomycosis a few years ago in a very old horse. The horse was brought to him simply with the history of being off its feed and losing condition, and the teeth were rasped and tonics given. There were no signs of improvement and in a day or two the animal developed cording of the lymphatics on the neck. As glanders was very prevalent in London, he had the horse tested with mallein, but there was no response. A day or two later the animal developed very marked pulmonary symptoms, and died in about forty-eight

hours after developing temperature and blowing. On post-mortem the lungs were found to be practically filled with botriomycotic nodules from the size of a golf ball to the size of a pea. Evidently the condition was of old standing. Whether the disease was secondary from a previous tumour he did not know, but there was no history of a botriomycotic tumour elsewhere, and none could be found on post-mortem. He did not know whether it was possible for primary botriomycosis to affect the lung. The case was seen by a County Council inspector, who sent portions of the lung to the College at Camden Town, and he believed Sir John McFadyen said it was a case of botriomycosis.

Prof. ALMOND said he had been reminded of a case he had under observation in a cart horse in which there was what might be called a cold tumour in the forearm. It had never caused any pain, and the animal had not been lame and was still at work daily. The forearm was about three times its natural size. The swelling was diffused, and he should like to know whether it was possible it was due to botriomycosis.

Prof. WOOLDRIDGE, in reply, thought the cases of tumours of the shoulder which the President was able to get to work again within three weeks were probably not botriomycosis at all. In cases which were botriomycosis the President appeared to be particularly hopeful. He himself should never like to promise a client to have an animal ready for work in three weeks without surgical interference, with any idea of being able to perform what he promised.

The PRESIDENT said the case that he alluded to were hard fibrous tumours with openings from five to six inches deep.

Prof. WOOLDRIDGE said he could not recall a case where he had to resort to that line of treatment with anything like the same good results. He had suggested in the paper that it was not the right thing to cut all shoulder tumours out, and that a good many cases would respond to local treatment without the necessity of making a wound into which one could insert two fists. He did not like to operate until he knew it was a well established case of botriomycosis, and unfortunately that was the most frequent condition in which he got the cases. In the majority of cases where the disease was obviously established the knife was the only thing, but cases which were hot and painful might have the same treatment as an ordinary abscess, because many cases were only abscesses and not botriomycosis. With regard to Mr. Almond's remarks as to leaving long ends to ligatures, he never did anything else. In the particular case he had referred to in the paper there were long ends several inches below the scrotal wound, but that was not the trouble; the trouble was the fact that the ligature was transfixed, and no amount of tension on the end of the ligature would draw it through. It was the transfixation he wished to warn people against. With regard to the enlarged forearm, he should say it was most probably not botriomycosis. The case appeared to have been in existence for at least two years without any evidence of fistulæ or deep abscesses, or discharge of any kind, and there was no surface wound. With regard to Mr. Saunders' question as to the method of castration in which scirrhus cord was most common, it was one he could not answer; every method had been said to be the chief cause. Mr. Saunders had referred to the fact that by the use of the hot iron he had had less scirrhus cord than before; other practitioners said that the hot iron was the chief cause of scirrhus cord, not so much the iron itself as the fact that scales from the iron might be left on the end of the cord and act as a centre of irritation. It really did not matter what method was adopted, because without the entry of the specific organism there would be no botriomycosis, and that organism could get in no matter what method was adopted. It was an accidental com-

plication. With regard to the raising of the scrotum and allowing the cord to fall back into the canal, he invariably raised the scrotum, not so much with the view of allowing the cord to fall back as to pour into it a certain amount of disinfecting fluid. He did not think the letting the cord fall back into the canal had any effect at all in the prevention of scirrhus cord. If it was an essential condition to avoid scirrhus cord, how was it it was not found where the operation of castration was practised standing? If care was taken to dissect very carefully in any gelding it would be found there had been adhesions between the end of the spermatic cord and the scrotal wall, so that the jerking back of the cord into the canal he did not think could have any particular effect. With regard to cutting the scrotum with a knife before using the hot iron, there were differences of opinion; many people, especially the older practitioners, prefer to cut the scrotum with a hot iron and not with a knife, not using the knife at all in the whole operation. In that way they said the wound would not heal before the end of the cord had healed, and therefore there was less likelihood of getting scrotal infection and scirrhus cord. Personally he thought there was something in that. A scrotum cut with a knife healed much more quickly than when cut with a hot iron. With regard to constitutional disturbance, he had not laid much stress upon it in connection with botriomycosis because he did not think it deserved it. The constitutional disturbance in Mr. Saunders' case was entirely due to the local abscess, and was of a passing nature. The case which lasted two or three months, mentioned by Mr. Saunders, was an illustration of the necessity for using the knife from the beginning. Mr. McIntosh's case of recurring tumour of the cord coincided with cases he himself had had of recurrence after a portion only of the tumour had been removed. In Mr. McIntosh's case it was possible the tumour at the inguinal ring might have been in existence at the time the operation was performed, but it was also possible that it might have extended owing to the fact that the original tumour was not cut out *in toto*. If it was at all possible to get to the limits it was inadvisable to be satisfied with cutting off a portion of the tumour in the hope that the rest would disappear. In some cases it would, but in other cases there would be nothing but disappointment. He felt very doubtful whether Capt. Jolliffe's case was one of botriomycosis, because gritty pus was never met with in such cases. As to chloroform, he thought it was an undeniable fact that the vessels were more dilated and there was more hæmorrhage, but it was not taken into account in the case of human subjects. In any extensive operation the patient would die from shock if he was not chloroformed. Hemostasis had attained such a pitch of excellence that the question was now not considered for a moment. It might be, too, that it was not so bad as some people would make out, and, personally, he did not dread hæmorrhage when operating for scirrhus cord under chloroform. He thought the idea was put forward more often as an excuse than a reason.

With regard to Mr. Perryman's remarks, there were undoubtedly a large number of shoulder abscesses which were not botriomycosis. Cases of chronic fibrous shoulder tumours with suppurating centres were almost invariably botriomycosis; but abscesses that were very painful and yielded to ordinary anti-phlogistic and puncture treatment and simple disinfection were not botriomycosis. It would be absolutely impossible to prove the cases in the early stage because the pus contained only cocci and no granules, which were the only characteristic things in connection with the organism. If the organisms were cultivated on artificial media and injected subcutaneously there would be only simple acute abscess formation, and if the disease was treated in the ordinary way there would be recovery. If it was neg-

lected, or the organisms entered more deeply, botriomycoma was formed with the granules. Mr. Perryman's experience of the use of iodine injection corresponded closely with his own. As to the treatment of multiple fibrous tumours about the body, the first hint he would give was to cut one out and have it examined microscopically, and he thought Mr. Perryman would find it was most likely a neoplasm and not a fibrous tumour. If it was a fibrous tumour fibrolysin might be given a trial, because it was being considered by some people as a specific for the reduction of fibrous tissue throughout the body. He had used it himself in a number of cases and had had recoveries in some cases and no change taking place in others, and whether the recoveries were due to it or not he was at present in doubt. With regard to Mr. MacDonald's case in which the lungs were affected, he did not think it was possible to get a case of primary botriomycosis of the lungs, and if the case was really botriomycosis there must have been some primary growth elsewhere. From the description of the case it appeared much more likely to be glanders, in spite of the fact that the animal did not react to mallein. At the meeting of the National Society in Carnarvon a case was shown which had been diagnosed some twelve months before as scrotal hernia, and was left alone for awhile. Then it began to discharge, and the diagnosis was changed to scirrhus cord, and the horse was sent to be operated upon as a demonstration at the meeting. Prof. Gofton operated, and he assisted him. It was a scirrhus cord to begin with, but as the dissection went on a piece of bowel was found, and it turned out to be a complicated case of scirrhus cord with hernia. The scirrhus cord was closely adherent to the bowel, and had to be carefully dissected away, and the ring was closed. The horse lived a fortnight afterwards and did not die of peritonitis, as was expected, but from purpura hæmorrhagica.

AMALGAMATION OF VETERINARY SOCIETIES.

A letter was read from Prof. Gofton with regard to the affiliation of the Society with the National Veterinary Association under the new rules.

The PRESIDENT explained that the Society had already approved of the scheme.

Prof. WOOLDRIDGE said he had proposed at the last meeting that the matter should be placed on the agenda in order that attention might be more clearly drawn to it, and that no Fellow of the Society should be able to say that he had not had an opportunity of expressing an opinion on the subject. He moved, "That the Society affiliate with the National Veterinary Association under the new rules."

Prof. ALMOND seconded the motion, which was carried unanimously.

On the proposition of Mr. Salusbury Price, seconded by Mr. McIntosh, the consideration of a letter from the Association of Veterinary Officers of Health was postponed.

A vote of thanks having been accorded to those gentlemen who had brought forward morbid specimens and to Prof. Wooldridge for his instructive and interesting paper, the meeting adjourned.

HUGH A. MACCORMACK, *Hon. Sec.*

VICTORIA VETERINARY BENEVOLENT FUND

The quarterly meeting of the Council was held at 10 Red Lion Square, on Thursday, January 11. There were present: Messrs. W. Freeman Barrett, T. G. Huntley, G. A. Banham, F. Hobday, F. W. Garnett, P. J. Simpson, S. Wharam, S. Stockman, S. H. Slocock, F. L. Gooch, H. Sumner, J. Macqueen, J. R. U. Dewar, and Wm. Shipley, *Hon. Sec.*

The minutes of the last meeting were read and confirmed.

The Secretary was requested to return their votes to the Treasurer of the London Orphan Asylum with a view to obtain support for one of the Fund's candidates on some future occasion.

Grants were made in the following cases. To Mrs. H. the sum of £10, to meet certain liabilities; to Mrs. F. J. B. the sum of 7/- per week; a similar sum to Mrs. N. J. B. Other cases were left over for further enquiries to be made. A temporary balance sheet was presented with the view of endeavouring to alter the term of the financial year from March 31st to December 31st.

It was decided to continue the relief to all old recipients, the Secretary to keep in touch with them, and to report when occasion requires.

The SECRETARY presented a short report on the distribution of the work and appealed to the members of Council and members of the profession to put some individual work into the Fund, in order to increase the number of annual subscribers, and also to have some members interested especially in cases of distress, to bring to the notice of poor widows the objects of the Fund. It was felt many cases of distress existed which did not come to the Council's notice. The list of annual subscribers must be considerably increased to meet the present expenditure, and to prepare for further fresh claims.

It was interesting to note that on the 31st March, 1911, we had only 115 annual subscribers, contributing £103 13s. Three Veterinary Medical Societies contribute £9 9s., making the annual income £113.

Whilst appreciating the kind grants from the various medical societies, it is desirable to obtain more individual interest, as some members of the profession feel that if their Society votes a sum their responsibility to the fund ceases.

The geographical distribution of the supporters of the fund is interesting. London and Middlesex furnishes twenty subscribers, Norfolk ten, Warwickshire and Yorkshire five each, Essex, Kent, and Surrey four each. Some few others with three, two, or one subscribers. There are no subscribers from fifteen counties; Scotland has only three, Ireland four. There are no subscribers in Wales. I hope some one in that district will take an interest in our fund. We have no recipients in the Principality, evidently it is a district where the operations of our fund are unknown. I shall be only too glad to give any information to any one interested.

Since the 31st March I am glad to say we have increased our list of new annual subscribers to 56.

I have also received over £40 in donations. One gentleman has offered to give £5 if I can induce ten others to do the same in order to ensure £1 a week for the following financial year.

I wish to mention that under Rule 4 all donations must be invested. I must ask the Council to consider this Rule, and also Rules 10, 28, and 17, at their next meeting.

DONATIONS AND SUBSCRIPTIONS OCTOBER TO DECEMBER 31ST, 1911.

The fifth annual meeting of the Georgia State Veterinary Association was held at Atlanta, December 21 and 22 last, and the question is how did they do it? How did they get into two days the amount of literary work set forth in their program? To be sure their secretary is a "live wire," and that counts for a whole lot in any organization. He says to the members, "Your interest is at stake. Parasites alone expect to reap where they don't sow."—*A. V. Review.*

Department of Agriculture and Technical Instruction for Ireland, (Veterinary Branch), Dublin, Jan. 22, 1912

NOTE.—The figures for the Current Year are approximate only.

* As Diseased or Exposed to Infection

Anthrax.

A fat bull belonging to Mr. Brinkworth, of Common Farm, Wroughton, was seized with anthrax while being driven to Swindon Christmas Fat Stock Show, and had to be killed. William Ledbury, the cowman, got some blood on his hands and has succumbed to the same terrible malady. He leaves a wife and eight children.

On Monday, January 1st, a heifer belonging to Mr. William Giles, Spittal Farm, Cricklade, was found dead at the farm. The police were informed, and later Mr. Broad, of Marlborough, who is acting as local Veterinary Inspector for the time being, examined the carcass and certified that the animal had died of anthrax. The carcass has been cremated.

Mr. Brookes, veterinary surgeon, stated that on Friday week a bullock died at Shrewley Barn, Warwick, and smears were sent to the Board of Agriculture, who certified a case of anthrax. The use of foreign food stuffs could not be traced, and there was no evidence that a case of the disease had ever occurred on the farm before. The bullock was fed on home-produced food stuffs.

A heifer was found dead on the farm of Port of Spittal, near Stranraer, occupied by Mr. James Downie. The cause of death was certified to be anthrax, and the carcass was accordingly cremated under the supervision of the veterinary inspector for the district.

A fat heifer fell ill and was killed at Swale Farm, near Thirsk. Mr. Pratt, the chief veterinary inspector of the North Riding, who made a microscopical examination of the blood, certified the case as anthrax.

Veterinary Examination of Clydesdales.

At a meeting of the Highland and Agricultural Society held on 10th inst.:

Mr. W. S. Ferguson moved as follows:—"That the rule adopted by the directors in April last, providing that the grant given by this Society will be available only for stallions which, for the year to which the grant applies, are registered in the Register of Certified Draught Stallions published by the Board of Agriculture, be rescinded." Mr. Ferguson said they were all strongly in favour of having sound horses, but he pointed out that if this rule was to stand there were local societies which would have to forego the grant given by the Highland and Agricultural Society. They were very well aware, as practical men, that some of the best of their aged stallions would not pass the test that was made. He knew of a case where they had two or three stallions hired, and they were giving the highest price for one that would not come through the test. He (Mr. Ferguson) asked them to rescind this resolution, and let them get their grant. A number of horses had been engaged for next year, and if their resolution was carried out they would have to be accompanied by a certificate which even the owners would decline to give. (Laughter).

Mr. W. T. Malcolm, in seconding, said it might be that they would get an occasional unsound stallion, but taking the breed as a whole, he thought they were wonderfully sound. He questioned if they would get a sounder animal anywhere than a Clydesdale stallion. That high degree of soundness had not been obtained by veterinary inspection, but by the hardheadedness and skill of the farmers of Scotland, who had made the breed what it was. He thought their proposed rules were unworkable, and that owners would be justified in declining until they knew who was to examine their horses. After the exhibition which they had recently at Dumfries he for one had no great faith in veterinary inspectors. He would have more faith in the skill and knowledge of their farmers and judges, who were constantly going

about shows, knew what was wanted, and how it was to be obtained. They had done very well by that class in the past, and he did not see why they should not be similarly trusted in the future.

Mr. John Marr moved that the Society adhere to its former resolution. He would like to ask Mr. Ferguson if he meant to encourage them to breed from unsound horses? [Mr. Ferguson: No]. What then did he mean? The step that the Society took in April was in the right direction. It was a reasonable thing to expect that the stallions they bred from should be sound horses. The Society would not be doing a good thing for the trade if they went back on the wise resolution which they passed in April. It was said that Clydesdale horseowners were averse to vetting. If they could not produce horses to stand the test let them want the premiums.

Capt. Gilmour, jr., of Montrave seconded. He had, he said, taken a good deal of interest in this matter, and as a member of the Advisory Committee to the Board of Agriculture and Fisheries, he urged Clydesdale owners to do their utmost to make the breed conform to the requirements of the Board.

Mr. J. M. Martin was inclined to congratulate Mr. Ferguson on his courage. On a previous occasion he could not find a seconder. In the interval he had been able to double his forces—(Laughter)—but he hoped he would not be able to treble them for the reasons which had been stated by Mr. Marr and Capt. Gilmour. Mr. Mr. Martin then referred to the success which had attended the vetting of Shire horses, the average of animals coming through the test being very high. It had been said that the stallion owners would not support them if this rule was adhered to, but he would remind the Board that they had the breeders to consider, who formed a much larger circle than the men who owned entire horses. When the societies came into line the stallion owners would do the same. (Hear, hear).

Mr. C. M. Cameron proposed that the rule should apply to stallions three years old and under.

Mr. Alexander Cross said that if Mr. Cameron included four-year-olds he would second his motion.

Mr. Cameron agreed to this.

In the course of further discussion, Mr. Marr pointed out that horses of two, three, and four years old had defects which sometimes did not become manifest at these ages.

On a vote being taken between Mr. Ferguson's motion and that of Mr. Marr, the latter was carried by 18 to 5.

Mr. C. M. Cameron's motion that all stallions of four years old and under should be registered in the register of certified draught horses published by the Board of Agriculture was then put against that of Mr. Marr, but the latter was again carried by 12 votes to 10.—*The Scottish Farmer*.

On the Value of University Training.

Sir Jonathan Hutchinson, in a long and interesting personal note on the late Dr. Hughlings Jackson (*Brit. Med. Journ.*, Dec. 9) says:

"As was natural, Jackson and I often discussed together the question as to whether we had regretted in later life our not having received any university training. Neither of us had been even to any high-class school, and both had, I believe, ended our educational curriculum at the age of 17, when we were apprenticed and became medical students. We thoroughly recognised the advantages offered at the larger Colleges: but, in attempting to strike a balance of loss and gain, Dr. Jackson was always unflinching in his avowal that he was glad he had not been sent to a university. He held that by exemption from over-teaching his mind had retained more of freedom and energy than might otherwise have been the case."

Rigs as Sires.*To the Editor of The Scottish Farmer.*

Sir,—I am glad that so experienced an authority as "Westtoon" has entered a *caveat* against the theories propounded on this question, in your issue of 23rd December. Your two veterinary correspondents are much more guarded in their replies to "Breeder" than you yourself in "Current Topics." I think "Reviresco" is mistaken as to what "Breeder" means by a rig. The term "rig" is very generally used—at least in Scotland—for a stallion or ram with only one testicle down, and no doubt that is what "Breeder" inquires about, and what Mr. Greenshields refers to. "Reviresco" does not dogmatise, merely stating that daughters of a rig would "likely" reproduce the paternal defect. Also, that there would be "a certain amount of risk" in using a rig. I can only say that this has not been my experience, either in sheep or horses. I have, like Mr. Greenshields, used sheep "hanging one," with quite satisfactory results. I do not recollect that I ever used a horse rig, but this was from no prejudice against them, as I have seen plenty of them and of normally-developed offspring, never hearing of any special tendency to produce the defect. Perhaps some owners or leaders of long-dead rigs could give more definite information, from their practical experience. Should this meet the eye of "Donald," who was so long stud groom at Urie, he will, no doubt, remember a rig, bred and owned by the late Colonel Findlay of Easterhill and Boturich, at Kenmuir, and used as a stallion. Did he leave more rigs than usual? I think he was Black Prince (56), which, I see, has apparently an alias in Prince Charlie (630). Of course, if "Breeder" speaks by the book, when stating, of the rig he mentions, that "a great many of last year's foals had nothing under them at all," no prudent breeder would use this horse, but in a somewhat prolonged breeding experience, on a fairly extensive scale, I have never seen an animal so bereft by nature.

You raise a very important question when you suggest the possible disqualification—on the ground of unsoundness—of an animal with only one testicle down. Certainly, if there is any danger of this, in the absence of a schedule, the sooner every society adopting veterinary examination of exhibits frames a schedule, the better. Some of your older readers may recall the incident, at the H. and A. S. show at Dumfries in 1870, when Rantin Robin (685) was protested by the owner of another competitor, on the ground of his being a rig, but the protest was not sustained, and the horse remained winner in the aged class. This was, I think, the only occasion on which the H. and A. S. adopted the system of universal vetting of prize-winners in the horse classes, and the resulting pandemonium was such that the society has never had the courage to revert to the practice. Had Rantin Robin been condemned, and breeders consequently refused to use him, we should have been deprived of the good class of daughters he left, while I am not aware that he bred rigs.

You write: "Unless an entire horse can beget his species, he is not entire." There is no obstacle to their reproducing freely, in the case of most rigs, and as "Reviresco" indicates, a rig with the only visible testicle removed may get stock. I do not know that your assertion would stand examination, however, any more than many others, confidently stated, and, at first sight, apparently incontrovertible. We all know of various horses, quite normally developed, which have left their country for their country's good, and crossed the Atlantic, because they had absolutely failed to get stock. Would any court of law or jury of experienced farmers support a plea that these were not entire horses? Possibly, under certain circumstances, a sale might be annulled

on the ground that the animal was useless for the purpose for which it was sold, but that is a different matter.

I should advise "Breeder" to prefer a fully developed stallion when of equal merit with a rig, but to prefer the latter where he is the better horse in other respects. I have heard it stated by old farmers and shepherds that rigs get more ewe than tup lambs, but I do not know that this could be substantiated.—Yours, etc.,

KNOWLEDGE SEEKER.

Veterinary Examinations.

At a meeting of the Southampton Town Council, held on Wednesday, 17th inst., the Tramways Committee reported having considered the tenders for two draught horses. Two it was recommended by a Sub-Committee should be purchased, and in regard to the third, offered by Mr. C. Sheppard for £58, it was reported that Mr. Sheppard had obtained a satisfactory report from an independent veterinary surgeon, and the Sub-Committee in the circumstances considered it advisable to engage the services of a veterinary surgeon residing outside the borough. This surgeon examined the horses purchased from Mr. T. Richards, Mr. W. Johnson, and the animal submitted by Mr. C. Sheppard. These were submitted later; also the certificates of Mr. G. F. Gould upon his examination of the horses in question and communication applying to be furnished with a copy of Mr. Tutt's certificates, as in case of any great variance between Mr. Tutt's and his own certificate he should like to apply to the Royal College of Veterinary Surgeons to appoint a Professor to examine the animals. It was resolved: (a) that the reports of the Sub-Committee be adopted and confirmed; (b) that the action of the Sub-Committee in engaging Mr. J. B. Tutt be confirmed; (c) that the brown gelding submitted by Mr. C. Sheppard be purchased at £58; (against)—Councillor Moulard; neutral—Councillor Bonner; (d) that a copy of Mr. Tutt's certificate be furnished Mr. Gould as requested.

Alderman Dunsford, the spokesman of the Committee, complained of difficulties in regard to the purchase of horses for the permanent way department. Several animals were tried, and upon examination one was returned. The owner was aggrieved, and sent the certificate of an independent veterinary. There being a dispute the Committee called in an independent veterinary Mr. Tutt, of Winchester, whose report largely agreed with that of the Council's officer.

Mr. G. F. Gould, the Council's veterinary surgeon, wrote enclosing another certificate dealing with the animal, and suggesting that the opinion of the President of the Royal College of Veterinary Surgeons be obtained, and offering to pay the fee if wrong.

Mr. Blakeway suggested that a Committee of inquiry should deal with the matter, as there seemed to be a desire to purchase the horse in spite of the veterinary surgeon's opinion. The matter was important, as they were buying many horses for the works department. He moved that the matter be considered by an independent Committee before any horses were purchased.

Alderman Dunsford said that two horses had already been purchased, the Committee being given power to act.

Mr. Brown asked for the reading of the veterinary reports, which was done by the Town Clerk.

Mr. Weston said that Mr. Gould had suggested that the opinion of the President of the Royal College of Veterinary Surgeons be obtained, and had offered to pay the fee if he was wrong. He moved that the offer be accepted.

The proposition was seconded, and it was agreed that the matter should remain in the hands of the Mayor and Town Clerk.—*The Hampshire Advertiser.*

ROYAL COLLEGE OF VETERINARY SURGEONS

NOMINATIONS FOR ELECTION TO COUNCIL, JUNE, 1912.

BURT, WALTER, Jr., Brighton, Sussex.
 CLARKSON, J., Garforth, nr. Leeds.
 DEWAR, J. R. U., Prof. Edinburgh.

 Lond : April, 1867.

Death occurred on January 22nd, from diabetic coma, at the age of 68 years.

CORRESPONDENCE.

WHAT IS THE NORMAL TEMPERATURE OF THE OX?

Sir,

I have been looking in vain for some time past for an article which I remember reading some few years ago in a veterinary periodical on the above subject, in which, if I remember correctly, the author proved to his own satisfaction that the normal temperature of the ox was above rather than below 102 F.

Having recently had the opportunity of taking the temperature of 122 apparently healthy calves living under natural conditions in this country, I thought it might possibly be of interest to record that their temperature worked out at a mean of 100.5 F. The highest and lowest temperatures recorded were 99 and 103 deg. respectively. The ages of these calves varied from 2 to 24 months, with an average of 8½ months, so that one would not have been surprised if the mean in these young animals had proved to be a little above what is usually accepted as the normal temperature in the ox, viz., 100—102 F.

I shall be much obliged if any of your readers can refer me to any article similar to that to which I allude.—I am, sir, yours faithfully,

F. WARE, L.C.V.D.

Madras, India.

CRUELTY PROSECUTION IN GLASGOW.

Sir,

May I refer in your columns to a case heard at the Justice of the Peace Court, Glasgow, on the 16th January? A contractor in the East End of the City was summoned at the instance of the R.S.P.C.A. for working a horse suffering from "disease and lameness in the off fore leg and foot." The charge was found proven: the Justices commenting on the case, remarked that it was of so trifling a character that they would content themselves with imposing the nominal penalty of 10/- fine.

I had performed the sidebone operation on both fore feet on the morning of 21st December, 1911, and the horse was stopped in the street that afternoon. Giving professional evidence on behalf of the R.S.P.C.A., two veterinary surgeons of Glasgow said the lameness was caused by one of the saw lines in the off fore foot being so deeply cut that the sensitive laminae were exposed and bleeding. I am not concerned at present to dispute with these gentlemen as to whether the line was too deep or not, so I will not impugn either their good faith or their eyesight (eyes that can see sensitive laminae through a line in the hoof 1-24th of an inch in width deserve to be spoken of with respect), but perhaps one or other of them will give us his views on this operation for our guidance in the future, and for the benefit of our clients.—Yours faithfully,

DONALD CAMPBELL, M.R.C.V.S.

"THE PROTECTION OF ANIMALS ACT, 1911."

Sir,

This Act, which came into force on Jan. 1st, 1912, was apparently drawn up, became law, and has been actually employed without any attempt to secure any greater amount of justice to the person indicted than existed under previous Acts, and I venture to suggest that each member of the veterinary profession who has any considerable amount of experience in "cruelty cases" can testify to glaring cases of miscarriage of justice brought about by mendacious audacity, erroneous assertions, and appalling ignorance of the parties prosecuting—ignorance, I mean, of course, in respect of the subject in dispute. And unless some measures are adopted to ensure a greater amount of fair play than have hitherto been employed, a gross iniquity will be inflicted on a section of the British public.

Why should a person who "beats, overloads, etc., etc." an animal, or permits it to be so treated, be more culpable than he or she who, without any proper knowledge or humane thought, fires, blisters, cuts, punches, extracts some part of the animal anatomy, or causes torture by the administration of drugs, medicines, and nostrums, often with a more or less benevolent intent but frequently, I fear, in a spirit of sheer cupidity and the grossest ignorance as to the potentiality of the means or substance used, and the direct inappreciation of the results that are likely to ensue?

Then what about the Court being able to deprive a person of his animal which is his own property? Surely there should be some uncostly means of appeal to an independent and competent expert before any Court is capable of resorting to such drastic measures, because not only are the officers of the R.S.P.C.A. biased persons, but gentlemen of the legal profession acting for them far too often forget or ignore their legitimate functions of "eliciting the truth in order that the adjudicator may arrive at a fair and just decision," and resort to the most contemptible and unscrupulous methods merely in order to win their case and procure remuneration either in the shape of money or distinction for themselves: their clients integrity or welfare being in other respects quite a secondary consideration.

How will the gentleman who owns a hunter or a race-horse which has been ridden (overridden) to a "standstill," or even perhaps to death, killed while being (practically) compelled to leap a fence or brook, like the liability of becoming a victim of an exceptionally courageous "Society's officer," and having to pay the full money penalty and his horse confiscated, because he is "likely to do it again"?

It appeared to me that the question as to whether a man is likely to repeat an offence of this description will be rather a knotty one to decide.

Lastly, how will professedly Christian people have the "heart" to see their fellow animal-creatures persecuted, ruined and convicted as criminals, when they themselves are, as happens in many cases, committing and permitting in one form or another acts equally reprehensible, callous, and worthy of punishment, even although perpetrated under the cloak of zeal in the cause of humanity.

Trusting the veterinary profession will take active interest in the matter,—Yours faithfully,

A. H. ARCHER, M.R.C.V.S.

THE COLLEGE FINANCES—SUGGESTIONS.

Sir,

I notice our College is going rapidly from bad to worse financially, and am of opinion that the profession would have responded well and a considerable amount would already have been in hand had half-guineas been asked for. When the Council are prepared to accept 10/6 I am prepared to pay yearly, and the guinea I shall pay when compelled, and I think hundreds more in the profession are of the same mind. They could try and see how it worked and go on compulsion lines as soon as they get the power.—Yours

SAM CHAMBERS.

Kirkheaton.

Sir,

No member of our profession can read the report of the last Council meeting without more or less concern. Two points seem perfectly clear. *First*, the R.C.V.S. is drifting each year towards bankruptcy. *Secondly*, the passage of the new Bill, the chief object of which is to avert that supposed catastrophe, seems most unlikely.

Now, sir, I know it is said that "Fools step in where Angels fear to tread," but for the moment I will risk being classed as one with the object of provoking a discussion upon some alternative to the course our Council has decided to pursue.

I believe our present financial deadlock is the psychological moment for suggesting a way out of our difficulties. Let me preface my suggestions by reminding you that the educational advancement of our country is being, and will continue to be, largely determined by the fostering and stimulating influence of the Universities of the Kingdom. Almost every branch of higher education, except our own, has profited by that wave of intellectualism which is passing over these islands. If we are to share in the advantages which must come to those who ally themselves with this movement towards higher education we must be willing to take risks and, if necessary, make sacrifices in the hope that our profession, and ultimately the community, may reap the benefit. I suggest, therefore, that we:

1. Abolish the one portal system.
2. That each College or School become affiliated to the local University, and each University with an affiliated Veterinary College have the right to grant diplomas to practise.
3. That the expenses connected with the examination of students be defrayed by the University granting the diploma.
4. That the R.C.V.S. retain the right of granting the Fellowship Degree.
5. That we utilise the newly organised N.V.A. for all matters concerning veterinary politics. This organisation will be in much closer touch with the members of the profession through the veterinary societies than the present Council.

I venture to think that not a single member of the profession would in any way suffer if we attempted to thus reconstitute our constitution. Our prestige as a profession would be raised. Our financial embarrassment would be terminated, and ultimately the community at large would benefit by the more commanding influence we should exert upon matters bearing upon public health.

I shall be interested to see whether either you or your readers consider any such scheme practicable.—Yours faithfully,

PROGRESSIVE.

ROARING.

Sir,

After reading the discussion on Prof. Craig's paper on "Roaring," read before the Veterinary Association of Ireland in Dublin, in which I was very much interested, and seeing in the same issue my old friend Mr. Wallis Hoare fishing for information on the same subject, it has occurred to me that I might with propriety relate a case that I think will interest him, and may not be without interest to other members of the profession, especially after the discussion of the paper above referred to.

Some time ago, how long I need not say, as I know that my friend is not cynical enough to apply the term "neophyte" to me, I was called upon to make careful examination of a stallion, which beginning to be used for stud purposes, as his owner was somewhat suspicious, from what he had heard from the groom, that his wind was not right. On arriving at the place my first care was to see that he was in good health, and not suffering from any temporary illness, or affection of the heart. After satisfying myself on this point, I got the groom to take him out to a field with nothing on except an ordinary head collar, with a plain snaffle bit, and began to lunge him in a circle with a good long lead. From the very first or second round he began to whistle, slightly but quite distinctly, and though the sound was somewhat intermittent in character, yet it was so persistent that I was afraid that I could only have very bad news for his owner. I then put him back to his box and did some other work to fill in time for half an hour or so, then got him out again and gave him another even more severe trial, and this time he only twice gave the slightest indication of any abnormal sound as the result of this test. After another interval of about half an hour, which I filled in as best I could, I had him out again, still further increased the speed and the severity of the test, in fact I galloped him, as the saying goes, "to a standstill" without being able to get him to give the very slightest whimper, or make the smallest noise of any kind, which was a very satisfactory finish to such a doubtful beginning. In this case no curb bit could be blamed, as it was not used, no rider with bad hands could have been the cause, for no one was up, and no bearing rein or other gagging harness of any kind was in use and therefore could not be the cause. What I attributed this rather unusual experience to was the fact that the animal was a raw colt, was fresh, frisky, and inclined to be playful, that he was inclined also to set his "head on his neck" and arch the latter too much naturally, and in this way to a certain extent gag himself when going too fast, and that the noise disappeared as soon as he relaxed himself and got into his proper stride. I am not prepared, however, to dogmatise on the subject, and will be pleased to have any other more satisfactory explanation. The horse continued to be a sound animal—though he continued to make slight noises from time to time during exercise, or during periods of excitement. Of course all this has no reference whatever to the pathological condition of the larynx, which was the question more immediately under consideration, but as the animal may still be alive, for aught I know to the contrary, it is obviously quite impossible for me to make any remarks on this aspect of the subject, and must perforce be content to confine anything I have to say thereanent to the physical aspect of this case.—Yours,

ANDW. SPREULL.

A convenient and efficient
Embrocation.

Capsolin (P., D. & Co.)

is composed of capsicum, camphor, oil of turpentine, oil of cajuput, and croton oil, so blended with an emollient base as to ensure an active degree of counter-irritation without vesication.

A small quantity rubbed into the affected part till absorbed forms an excellent substitute for mustard poultices or hot fomentations, and is of great value in cases of

Capped Hock.	Rheumatism.
Inflamed Joints.	Sore Throat.
Periostitis.	Strangles.
Pleurisy.	Strained Tendons.
Pneumonia.	Synovitis.

Being free from poison it may be used with safety in parts which the animal may be inclined to lick.

A soothing and healing
Dressing.

Emollientine (P., D. & Co.)

is a combination of aluminium hydrate, carbolic acid, isarol, lead oxide, corrosive sublimate, and zinc sulpho carbolate, which is exceptionally successful as a means of reducing inflammation, mitigating pain, maturing suppurative processes, stimulating cell action, and promoting healing. It forms a most beneficial application in

Canker.	Mud Fever.
Cracked Heels.	Over-reach.
Garget.	Saddle Galls.
Grease.	Sore Shoulders.
Incised Abscesses.	Sprains.

Its bactericidal properties render it most effective in eczema, psoriasis and other parasitic diseases.

THE 'RECORD' PRECISION SYRINGE.

The FINALITY of Hypodermic and Serum Syringes.

"The "Record" Precision Syringe is a piece of delicate mechanical workmanship well deserving its name. It meets **all requirements as regards aseptic conditions and accuracy and it is always ready for use.**

It consists of **metal and glass** only. The glass barrel is ground inside perfectly true to cylindrical form. The Nickel vacuum piston is "ground in" into the glass barrel by precision machinery so as to fit hermetically, it slides smoothly, yet tightly, **without any lubricant.**

The cover is fixed on the cylinder with a **bayonet-fastening**; for the purpose of **thorough cleaning** it is provided with a segmental incision, by means of which it can be detached from the piston-rod by sliding it off side-ways. When **completely** taken apart the Record Syringe **forms 3 parts only: cover, piston and barrel.**

The **Needles** are provided with the original "Progressive" **flat** mounts. By this arrangement a good hold is afforded to the operator.

The fixing of the needle itself in the mount, by means of a smooth longitudinal guide arranged above the screw threads prevents the needle from breaking off in the mount.

EVERY SYRINGE IS GRADUATED BOTH IN C.C. AND 'MINIMS.

Practice Wanted

ADVERTISER is prepared to purchase for cash a genuine, well established practice returning £700 a year or over. Full investigation and good introduction must be given. Confidence observed. Address, 2201, V.R., 20 Fulham Road, London, S.W.

For Immediate Disposal

GENUINE small country practice, capable of increase, suitable house, stables etc., at low rent. Returns about £150. No reasonable offer refused to effect quick sale. Full particulars on application. Address, 1201 V.R., 20 Fulham Road, London, S.W.

Chlorodyne

FOR SALE, a large quantity of Chlorodyne, full strength, B. P. 1885, at 2/- per pound. H. J. Pratt, Wholesale Druggist, Cleckheaton.

PRACTICES FOR DISPOSAL

IN large Midland City. Genuine mixed practice returning £850 per annum, and shoeing business returning £750. Accountants certify profit of £650 per ann. Capital required about £1250.

WESTERN COUNTY. Receipts about £600 per annum. In present hands nearly 50 years. Advancing age sole reason for sale.

PURCHASERS ARE REQUESTED to call, or write stating their requirements, as we have numerous Practices on our Register which have not been advertised. *No charge* is made to purchasers.

SOUTHERN COUNTY. Easily worked practice returning £650 per annum. Convenient house with good yard, stabling, kennels, etc. Rent £85 or would sell freehold if preferred. Premium one years purchase, valuation optional. The vendor is well-known to us and the practice can be thoroughly recommended.

GOOD-CLASS practice in the West of London, returning £600 per annum. Well-situated house, rent £70. A partnership might be entertained with a suitable gentleman, but vendor would prefer to sell the whole practice.

WEST OF ENGLAND. Town practice held nearly 20 years by present incumbent. Receipts: 1910 £1172. Contracts produce £251. Good house containing 5 bedrooms, 3 recept. etc. garden, stabling. Working expenses light. Premium £1500.

SOUTH COAST. Country practice returning about £835 per annum, including appointments producing about £70. In present hands 24 years. The practice has been worked by an assistant who would remain if desired. Convenient house, rent £21, larger available if required. Premium £800.

LONDON, N. Very old-established practice returning about £1200 per annum. Good house and thoroughly convenient premises, rent £90. The practice is principally horse. Receipts are increasing. Premium one years purchase. This practice is well-known to us and can be recommended.

SURREY. Rapidly increasing, well-established practice returning about £1000 per annum. Small house with stabling, kennels, etc. Capital required, including valuation, will be about £1300. The practice is well-known to us and can be thoroughly recommended to a suitable man.

HIGH-CLASS mixed practice returning about £650 per annum. Good premises would be let on lease or sold if preferred. Premium £600.

PROSPECTUS, containing "*Hints to Vendors*" and "*Hints to Purchasers*," post free on application.

To Vendors.

WE make *no charge* unless a Sale is effected. If you have a genuine Practice you wish to sell quickly and without publicity we shall be pleased to place particulars on our Register.

No. 1230.

FEBRUARY 3, 1912

VOL. XXIV.

A PRACTITIONER'S STUDY.

Last week we published an article upon ovine abomasitis due to the *Strongylus cervicornis*, by Mr. E. G. Haskell, which deserves careful reading. It is of interest viewed merely as a contribution to the study of the still imperfectly understood life-history of the parasite in question and of the disease it causes; for it will be seen that the author's observations differ in some respects from the classic account given by M'Fadyean, the original discoverer of the strongyle. Mr. Haskell, for instance, reports finding "numerous free forms which appeared to be embryos" in the stomach contents; M'Fadyean found "neither free embryos nor larger sexually immature worms," but only ova and adult forms. Again, in his account of the symptoms and post-mortem findings of the disease, Mr. Haskell does not mention one feature noted by M'Fadyean and others, viz., the ingestion of sand or earth.

As regards treatment, also, Mr. Haskell differs from some observers in attaching a distinct value to certain drugs—some men doubt the utility of any medication in parasitic abomasitis. And, further, apart from all details of the article, there is one general feature which gives it value—its internal evidence of independent study and observation, which did not stop at the diagnosis.

Diagnosis alone satisfies most men. A few go further, and seek to compare what they see with the results recorded by others, and any one doing so, while he cannot fail to improve his own conception of the subject he works upon, may succeed in advancing the knowledge of the profession. It is not easy for the practitioner to attempt work of this nature—work always bordering upon, and apt at any time to develop into, actual research—but the difficulty varies a great deal in accordance with the subject attempted.

Many subjects are quite impossible to the ordinary working practitioner. But with others, the difficulties are not insurmountable, and parasitology is certainly one of those most accessible to the man in practice. It demands no such costly elaboration of apparatus as is required for a study like bacteriology; for the bulk of parasitological work, indeed, an ordinary microscope and very simple accessory apparatus will amply suffice.

The technique, for the most part, presents no great difficulty; while in town and country alike—especially in the latter—there is always an abundance of material for study. Parasitology is one of the numerous subjects for practical study which literally lie ready to the hand of almost every clinician; and the wonder is that comparatively so few men have taken it up. A decade or two ago, our members generally felt little interest in it: the increasing interest during recent years is a healthy sign.

TWO CASES OF FRACTURE OF THE FIRST RIB.

I.—A five-year-old mare, belonging to the Army Service Corps, was admitted to hospital on 23rd November, 1911, lame on the off fore leg, the toe only touching the ground, and no weight was put on the leg. An examination of the limb revealed nothing abnormal, except pain on pressure in the region of the shoulder—pain which did not seem to be due to anything existing in the limb itself.

When made to move the mare could bring the limb forward, but when any weight was put on it she sank down until the sternum almost touched the ground, with the leg pushed out in front, remaining in that position for a few seconds until she recovered herself on the other leg. About a fortnight later she was taken out of slings for further examination and showed the same symptoms. A fracture of the first rib was thought to exist, and the mare was destroyed on 15th December.

Post-mortem.—Fracture of the first rib on off side, about two inches from the vertebrae.

History.—The injury occurred when the mare was being driven in double harness in an ambulance waggon. The waggon was being turned round in a narrow road, and while in process of turning the mare seemed to stumble, according to the driver, and immediately afterwards was on three legs. As she was unable to walk, a horse ambulance was sent for, and the animal brought to the Station Veterinary Hospital.

I enclose some photographs of this case, which Capt. W. H. Nicol, A.V.C., kindly took for me.

II.—The other case was a troop horse of 5th Dragoon Guards. A six year old mare which had been running out at grass for two months prior to 12th December, 1911, the date she was admitted to hospital. She arrived late at night in a horse ambulance, in which she had got down *en route*, and was lying on the injured side—near side. She had to be carried from the ambulance into a loose-box, where she was laid on her off side, and made as comfortable as possible. The following morning it was thought best to destroy the mare as she was in great pain.

Post-mortem.—About two inches of lower end of first rib, on near side, showed signs of a chronic osteitis. The portion of the rib which articulates with the sternum was involved in the osteitis, two-thirds of the articular cartilage being absent, and a roughened bony surface remaining. Just above the portion of the rib which showed old standing inflammatory changes, viz., in the apparently healthy part of the bone, the rib was transversely fractured.

History.—It is not known how the injury occurred while at grass. For months previous to going out to grass this mare is said to have shown signs of pain when being "girthed up" in the Troop stables, and on several occasions fell down in the stall when this was being done. She is also said to have fallen down on more than one occasion when first mounted, but showed no sign of being unable to carry the man's weight, when actually at work.

The inflammatory changes referred to in the sternal extremity of the rib were of old standing, but the fracture was recent.

W. A. McDougall, Maj. A.V.C.
Station Veterinary Hospital, Curragh.
24th January, 1912.

ABSTRACTS.

A CULTURAL METHOD OF HYPER-IMMUNISING ANIMALS FOR THE PRODUCTION OF ANTI-RINDERPEST SERUM.

The manufacture of rinderpest anti-serum has hitherto been very expensive on account of the great wastage of control animals for the production of virulent blood for use as the hyper-immunising agent. Many attempts have been made to increase this material without increasing the expenditure of animals, one of which, viz., the use of "peritoneal washings," was recently mentioned in these columns in a note upon a paper by Major F. S. H. Baldrey. This method has led the same investigator to a further series of experiments, which he now describes in detail (*Journal of Tropical Veterinary Science*, Vol. VI., Part III.), and which have resulted in the discovery of a new method. Major Baldrey's conclusions are as follows:—

1. Anti-rinderpest serum can be prepared by the inoculation of virulent blood diluted with broth.
2. It appears possible that an active toxin is produced and excreted into the broth by the rinderpest organisms contained in the virulent blood, and by this means the results recorded are obtained.
3. This material or probable toxin is rapidly excreted, and so active that it appears to quickly inhibit any further growth of the rinderpest organism, destroying its virulence, and finally killing it.
4. The substance so obtained is very much more active than that obtained in virulent blood, so much so that it cannot be given subcutaneously with safety on account of the extreme inflammatory condition it sets up.
5. To use it as a hyper-immunising agent, doses are better given intravenously and gradually increased so that the "salting" is spread over a period of some two months or more.
6. The immune serum so obtained is powerful, but 15-20 per cent. weaker than that made by massive injections of virulent blood.
7. The method is an eminently practical one, and shows a great financial saving.

Regarding the last point, it may be added that,

should the method stand the test of extended use in the field, the financial saving it will effect will be enormous. It is estimated that, instead of the Muktesar Laboratory using some 200 to 250 control animals per month, 15 or 16 will suffice. This will represent a direct financial saving of 1,600 to 1,700 rupees per month, besides greatly increasing the available accommodation.

PHARYNGEAL PAPILLOMATA IN A DOG.

Tumours of the pharynx are rare in the small domestic animals. In cattle, numerous authors have recorded cases of tumours properly so-called, as papillomata, sarcomata, carcinomata, lipomata, and cysts, and also of infectious new growths such as those of actinomycosis and tuberculosis. But in the dog only a single case, reported in Cadéac's *Encyclopædia*, exists in veterinary literature. Hebrant and Antoine, of the Belgian Veterinary School, now record the following on account of its exceptional rarity.

The subject was a large dog, ten years old, which for some time had shown loss of appetite. The owner said that the general condition had always been excellent, but seemed to have become bad during the last few days, while the dog showed great difficulty in swallowing food.

Careful examination of the patient revealed nothing very marked. The temperature was normal, the pulse and respirations were calm, the functions of the abdominal viscera appeared satisfactory, and all the vital functions were executed perfectly. Despite this the animal was emaciated. There was no enlargement of the heart, and the urine contained neither albumen nor cylinders, thus enabling nephritis, which is common amongst old dogs, to be eliminated from the diagnosis.

The authors suspected a simple angina, and minutely examined the pharyngeal region. External inspection and palpation revealed nothing, and the interior of the pharynx was then examined by applying a mouth-gag and drawing out the tongue. The pharyngeal mucous membrane was absolutely normal; but it was seen that two tumours, fairly well detached, papillomatous in aspect, one attaining the size of a nut and the other that of a large pea, were situated upon the right lateral wall of the passage.

The authors immediately attempted to remove these growths by means of forceps and curved scissors, but found it impossible to reach them. They therefore postponed the operation till the next day, and in the meantime procured the instrument known in human surgery as the *amygdolotome*. This consists of two annular knives gliding one upon the other with a small fork gliding above them, the latter piercing the tumour to be removed and assisting to adjust it in position for the knives to divide it at its base.

By means of this instrument the mouth being kept open and the tongue well drawn out, the two tumours were removed in an instant. A rather abundant hæmorrhage appeared at this moment, and at the same time the animal fell into syncope. Artificial respiration, inhalations of ether, and tam-

ponnage with chloroform water soon rectified these accidents. After treatment consisted in painting the operative wounds with diluted tincture of iodine, the animal being kept meanwhile upon a milk diet. Four days after the operation, as all was going well, the dog was taken home again by his owner. —(*Annales de Méd. Vét.*)

[The authors do not definitely say that a microscopic examination of these tumours was made. They head their article as one on "Pharyngeal papillomata in a dog," and as the case was a very rare one, and occurred in a veterinary school, it is hardly likely that the diagnosis was not verified by the microscope.—*Transl.*]

SUPPURATIVE ORCHITIS AND EPIDIDYMITIS IN A HORSE.

Lecomte records (*Revue Vétérinaire*) a case of a horse which presented a voluminous engorgement of the scrotal region. When first seen, this swelling was merely œdematous, without heat or appreciable pain. An astringent treatment was prescribed.

Two days later, the symptoms were considerably aggravated. The animal was in an intense fever; and the œdema had become localised to the left testicular region, which was warm and very painful. Movement was difficult, and the limbs were maintained in abduction. Fœtid pus was escaping from the urinary meatus.

Not finding the fluctuation which is usually met in vaginalitis, the author diagnosed suppurative orchitis, and decided to remove the diseased testicle.

The operation was performed by torsion, after previously washing out the vas deferens and the urethra, which caused the evacuation of pus by the urinary meatus. Recovery was complete in eleven days.

A section of the testicle showed the existence of three abscesses, of the size of a nut, in communication with the seminiferous ducts. This indicated an ascending infection.—(*Annales de Méd. Vét.*)

INJURY TO RUMEN BY A FRACTURED RIB.

Enrico Sampoli records (*Il Nuovo Ercolani*) a case of an ox which fell upon declivitous ground with the head under the body, in such a way that the point of the left horn pressed into the left costal region without, however, leaving a visible external wound. The ox was extricated from this position with much difficulty, and immediately brought into a stall, where he showed no disturbance in general health.

Soon afterwards, however, an extensive emphysema of the skin developed on the left side of the body. At the highest point of this, about the eleventh intercostal space, a cone-shaped depression existed, running obliquely backwards to the twelfth rib. Here the skin was hairless and thinned.

In a few days the emphysema subsided; but at the region mentioned above a firm swelling remained, which grew progressively as time went on, and increased in size till it reached the dimensions of a man's head. At its upper edge, at the place

upon which the horn must have borne, the skin and underlying tissues now became necrotic; so that Sampoli could easily force in his finger and reach a spacious cavity filled with alimentary material and shreds of tissue. In the depth of this the upper part of the twelfth rib, which had been completely fractured in its middle third, could be felt detached from all the muscles. The lower portion of the bone had been displaced inwardly.

Soon afterwards the ox was slaughtered, and post-mortem examination showed that the lower portion of the rib had made a rent of about 2½ inches long in the rumen. An adhesive circumscribed peritonitis had afterwards, by the formation of a thick ring of connective tissue, led to union of the edges of this rent with the peritoneum, and so prevented the entrance of masses of food into the peritoneal cavity. This explained the comparatively slight effect of the injury upon the general condition of the animal, which ate normally and ruminated regularly until slaughtered.—*Berliner Tier. Woch.*

POLYMYOSITIS METASTATICA.

Emil Balla, of Budapest, records (*Allatorvosi Lapok*) the case of a lean St. Bernard dog which, after copulation, showed symptoms of paralysis. He could still, with assistance, raise himself upon his hind limbs, but he straddled the fore limbs and fell after a few steps. Both forearms showed spindle-shaped swellings, were very painful, and in some places were of a stony hardness.
